Abstract

We analyze an $hp$ FEM for convection-diffusion problems. Stability is achieved by suitably upwinded test functions, generalizing the classical $a$-quadratically upwinded and the Hemker test-functions for piecewise linear trial spaces (see, e.g., [12] and the references there). The method is proved to be stable independently of the viscosity. Further, the stability is shown to depend only weakly on the spectral order. We show how sufficiently accurate, approximate upwinded test functions can be computed on each element by a local least squares FEM. Under the assumption of analyticity of the input data, we prove robust exponential convergence of the method. Numerical experiments confirm our convergence estimates and show robust exponential convergence of the $hp$-FEM even for viscosities of the order of machine precision, i.e., for the limiting transport problem.

Subject Classification: Primary: 65N30, 65N12; Secondary: 35B25, 35C20
1 Convection-Diffusion Problem

1.1 Problem Formulation

In $\Omega = (-1,1)$ we consider the model convection diffusion problem

$$L_{\varepsilon} u_{\varepsilon} := -\varepsilon u_{\varepsilon}'' + a(x) u_{\varepsilon}' + b(x) u_{\varepsilon} = f(x)$$

(1.1)

with the boundary conditions

$$u(\pm 1) = a^{\pm} \in \mathbb{R}.$$  

(1.2)

Here $\varepsilon > 0$ is the diffusivity, $a(x)$ is, for example, concentration of a transported substance, $a(x)$ is the velocity of the transporting medium, $b(x)$ specifies losses/ sources of the substance and $f(x)$ is an external source term. Throughout this work, we make the following assumptions on the coefficients $a \in C^1[-1,1]$, $b \in C^0[-1,1]$: There are constants $\overline{b} \in \mathbb{R}$, $\underbar{a}$, $\gamma_1$, $\gamma_2 > 0$ such that for all $\varepsilon \in (0,1]$

$$a(x) \geq \underbar{a}, \quad b(x) \geq \overline{b}, \quad \min \{ \overline{a}, \underbar{a}^2 + 4 \overline{b} \varepsilon \} \geq \gamma_1^2,$$

$$\max \left\{ \frac{\overline{a} - \sqrt{\overline{a}^2 + 4 \overline{b} \varepsilon}}{2 \varepsilon}, 0 \right\} \leq \gamma_2.$$  

(1.3)

As we will also consider the adjoint problem of (1.1) (cf. Section 2 ahead) we stipulate the existence of $\overline{b}^* \in \mathbb{R}$ and $\gamma_1^*, \gamma_2^* > 0$ such that

$$a(x) \geq \overline{a} > 0, \quad b(x) - a'(x) \geq \overline{b}^*, \quad \min \{ \overline{a}, \overline{a}^2 + 4 \overline{b}^* \varepsilon \} \geq (\gamma_1^*)^2,$$

$$\max \left\{ \frac{\overline{a} - \sqrt{\overline{a}^2 + 4 \overline{b}^* \varepsilon}}{2 \varepsilon}, 0 \right\} \leq \gamma_2^*.$$  

(1.4)

(1.3) ensures the unique solvability of (1.1), (1.2) while (1.4) guarantees the unique solvability of the adjoint problem. Note that for given $a$, $b$, the constants $\gamma_1$, $\gamma_2$, $\gamma_1^*$, $\gamma_2^*$ exist under the assumption that the diffusivity $\varepsilon$ is sufficiently small.

The finite element approximation of (1.1), (1.2) for small $\varepsilon$ is nontrivial due to the singular perturbation character of the problem which manifests itself in two distinct phenomena:

First, the solution $u_{\varepsilon}$ exhibits a boundary layer near the outflow boundary $x = 1$; we will characterize the boundary layer behavior of the solution $u_{\varepsilon}$ more precisely in Section 1.2 ahead. The second difficulty arises from the well-known fact that symmetric variational formulations of (1.1), (1.2) based on $H^1_0$ as trial and test space are not uniformly stable with respect to the parameter $\varepsilon$. One possible remedy is the use of streamline-diffusion techniques which amount in effect to a nonconforming method (see, e.g., [14] and the references there). Crucial to the convergence analysis of streamline diffusion FEM are $H^2$ regularity of the solution and certain elementwise inverse inequalities which allow to control the higher order derivatives introduced into the variational formulation through the streamline-diffusion term. While this idea is, in principle, also feasible for $p$- or spectral element methods, the convergence rates obtained that way will be suboptimal due to
the higher loss of derivatives in inverse inequalities for polynomials. This is even more
pronounced for the combined \(hp\)-type FEM, in particular in two and three dimensions,
where the optimal approximation of boundary layers mandates elements of arbitrary high
aspect ratio (see [16]) for which suitable inverse inequalities do not seem to be available.
The \(hp\)-FEM is nevertheless very attractive for such problems, since \(hp\)-trial spaces have
approximation properties superior to both, \(h\)-version FEM and spectral methods. For
example, \(hp\)-FEM can be shown to approximate boundary layers and corner singularities
at a \textit{robust exponential convergence rate} (see [15, 16]). This will also be true for any
stable projection method based on these trial spaces. To achieve stability, we use Petrov-
Galerkin methods where test- and trial-spaces are distinct, an approach that has been
followed by numerous authors in the finite difference and finite volume setting (see [12,
14, 11] for an account of this work and many references). We base the \(hp\)-FEM on the
variational framework from [18, 19] where the \(h\)-version FEM was analyzed and optimal
convergence rates, uniform in \(\varepsilon\), were shown. Asymptotically exact \(h\)-version a-posteriori
error estimators for this variational formulation have also been developed in [19] and
it was shown that the numerical solutions exhibit few spurious oscillations and good
pointwise convergence. The crucial ingredient in [18, 19] was the construction of suitable,
upwinded test functions by asymptotic analysis of the elemental adjoint problem. The
generalization of this asymptotic analysis to high order elements and higher dimensions
is not straightforward.

Here we propose therefore a fully numerical method. More precisely, we show how for \(hp\)-
trial spaces with any mesh-degree combination sufficiently accurate \textit{approximate upwinded
test functions} can be stably computed. The calculation of the test functions is completely
localized to either a single element or a patch of elements and done by a least-squares
like method (which is uniformly stable in \(\varepsilon\)). This can be simply performed as part of the
usual element stiffness matrix generation in the \(hp\)-FEM. Our analysis shows that a) the
approximate test functions thus obtained do ensure stability and that b) already fairly
crude approximations of the test functions suffice, so that the work spent in computing
these test functions can be expected to be moderate. Most importantly, no analytical
input in the form of asymptotic expansions or boundary layer functions is necessary –
the method is fully computational and conceptually generalizes readily to two- and three-
dimensional problems. Here we analyze the method in detail for the one-dimensional
model problem (1.1), (1.2), where new regularity results for the solution allow us to prove
robust exponential convergence. The analysis for two and three dimensional problems
will be given elsewhere [10].

1.2 Regularity

Let us consider (1.1) on \(\Omega = (-1, 1)\) with \textit{analytic} input data \(a(x), b(x), f(x)\) satisfying
\[
\|a^{(n)}\|_{L^\infty(\Omega)} \leq C_a \gamma_a^n \quad \forall n \in \mathbb{N}_0 \tag{1.5}
\]
\[
\|b^{(n)}\|_{L^\infty(\Omega)} \leq C_b \gamma_b^n \quad \forall n \in \mathbb{N}_0 \tag{1.6}
\]
\[
\|f^{(n)}\|_{L^\infty(\Omega)} \leq C_f \gamma_f^n \quad \forall n \in \mathbb{N}_0 \tag{1.7}
\]
for some constants \(C_a, C_b, C_f, \gamma_a, \gamma_b, \gamma_f > 0\). Assumptions (1.3) and (1.5)—(1.7) ensure the
existence of a unique, analytic solution \(u_\varepsilon\) of (1.1), (1.2). The purpose of this subsection
is to illuminate the regularity properties of \( u_\varepsilon \) in dependence on the parameter \( \varepsilon \) and the constants of (1.3), (1.5)–(1.7). These regularity results are necessary for the proof of robust exponential convergence of the \( hp \)-FEM obtained in the present paper. Although regularity results related to the ones presented here are in the literature ([14], [12]), the specific derivative bounds seem to be new (see also [9] for the related case of a reaction diffusion equation).

The solution \( u_\varepsilon \) of (1.1), (1.2) is analytic on \( \Omega \); however, for small values of \( \varepsilon \), it exhibits a boundary layer at the outflow boundary. This boundary behavior can be characterized with the aid of asymptotic expansions: For any expansion order \( M \in \mathbb{N}_0 \), we have the standard decomposition (see, e.g., [4])

\[
  u_\varepsilon = w_M + C_M u_\varepsilon^+ + r_M. \tag{1.8}
\]

Here, \( u_M \) is the asymptotic part given by

\[
  w_M := \sum_{j=0}^{M} \varepsilon^j u_j + \alpha^- e^{-\Lambda(x)}
\]

\[
  u_{j+1}(x) := e^{-\Lambda(x)} \int_{-1}^{x} \frac{e^{\Lambda(t)}}{a(t)} u'_j(t) \, dt 
  \quad j = 0, \ldots, M - 1
\]

\[
  u_0(x) := e^{-\Lambda(x)} \int_{-1}^{x} \frac{e^{\Lambda(t)}}{a(t)} f(t) \, dt
\]

\[
  \Lambda(x) := \int_{-1}^{x} \lambda(t) \, dt
\]

\[
  \lambda(x) := \frac{b(x)}{a(x)}
\]

The outflow boundary layer \( u_\varepsilon^+ \) solves the problem

\[
  L_\varepsilon u_\varepsilon^+ = 0 \quad \text{on } \Omega, \quad u_\varepsilon^+(-1) = 0, \quad u_\varepsilon^+(1) = 1, \tag{1.9}
\]

and \( C_M \) is given by

\[
  C_M := \alpha^+ - w_M(1). \tag{1.10}
\]

Finally, the remainder \( r_M \) is given as the solution of

\[
  L_\varepsilon r_M = \varepsilon^{M+1} u'_M \quad \text{on } \Omega, \quad r_M(\pm 1) = 0 \tag{1.11}
\]

Note that for \( M = 0 \) the function \( w_0 \) solves the limiting transport problem given by (1.1) with \( \varepsilon = 0 \) and the boundary condition \( w_0(-1) = \alpha^- \).

**Theorem 1.1** Let \( u_\varepsilon \) be the solution of (1.1), (1.2). Then there are constants \( C, K \) depending only on the constants in (1.5)–(1.7) and on the constants \( a, \gamma_1, \gamma_2 \) such that

\[
  \|u_\varepsilon^{(n)}\|_{L^\infty(I)} \leq C K^n \max(n, \varepsilon^{-1})^n \quad \forall n \in \mathbb{N}_0 \tag{1.12}
\]

\[
  |u_\varepsilon^{(n)}(x)| \leq C K^n \max(n, \varepsilon^{-1})^n e^{-\varepsilon(1-x)/(2\varepsilon)} \quad \forall n \in \mathbb{N}_0, \quad x \in I. \tag{1.13}
\]
Furthermore, under the assumption $0 < \varepsilon MK \leq 1$, the terms in the decomposition (1.8) satisfy

\begin{align}
\|w_M^{(n)}\|_{L^\infty(\Omega)} & \leq CK^n n! \quad \forall n \in \mathbb{N}_0 \quad (1.14) \\
\|r_M^{(n)}\|_{L^\infty(\Omega)} & \leq C\varepsilon^{1-n}(\varepsilon MK)^M \quad n = 0, 2 \quad (1.15) \\
|C_M| & \leq C \quad (1.16)
\end{align}

The proof of Theorem 1.1 is given in Appendix B.

## 2 Variational Formulation

Without loss of generality, we may analyze (1.1) with homogeneous Dirichlet data

$$\alpha^\pm = 0 \quad (2.1)$$

by the standard argument of seeking $u_\varepsilon$ in the form $u_\varepsilon = \bar{u}_\varepsilon + u_0$ (where $u_0$ is linear and satisfies the boundary conditions (1.2)) and then noting that this leads to (1.1),(2.1) for $\bar{u}_\varepsilon$ with the same operator $I_\varepsilon$ and suitably adjusted right hand side $f$ which is analytic and independent of $\varepsilon$.

To motivate our variational formulation, we observe that multiplication of (1.1) by a test function $v$ and twofold integration by parts gives a so-called very weak variational formulation: Find $u \in L^2(\Omega)$ such that

$$B(u, v) := \int_\Omega uL^*_\varepsilon v dx = \int_\Omega f v dx =: F(v) \quad \forall v \in H^2 \cap H^1_0(\Omega).$$

Here, $L^*_\varepsilon$ denotes the adjoint of $L_\varepsilon$, i.e.

$$L^*_\varepsilon u = -\varepsilon u'' - a(x)u' + (b - a')(x)u \quad (2.2)$$

which is defined when $a \in C^1([-1, 1])$. There are several drawbacks with FEM based on very weak variational formulations: first, $a'$ is in general not globally continuous, but only elementwise smooth (if it stems, for example, from linearization of the nonlinear problem around a FE-approximation of $u$), second, to obtain a good test-space for a given trial space of possibly discontinuous functions, a global adjoint problem must be solved for each basis function and third, the essential boundary conditions (1.2) are generally not satisfied by FE solutions. This leads us to a formulation which is situated “between” the weak one based on $H^1_0 \times H^1_0$ and the very weak one based on $L^2 \times H^2 \cap H^1_0$.

We present Sobolev spaces with mesh-dependent norms introduced in [19]. For a collection of nodes $\{-1 = x_0 < x_1 < \ldots < x_N = 1\}$, we introduce the notation $I_j := (x_{j-1}, x_j)$, $h_j := |I_j| = x_j - x_{j-1}$, $m_j = (x_{j-1} + x_j)/2$ for $j = 1, \ldots, N$. The elements $I_j$ form a mesh $T = \{I_j : j = 1, \ldots, N\}$ on $\Omega$. Let further $\{\rho_j\}_{j=1}^{N-1}$ be a sequence of positive numbers and set $\rho := \rho_1 + \rho_2 + \ldots + \rho_{N-1}$, $h := \max \{h_j : j = 1, \ldots, N\}$. Then we define the trial space $H^2_\rho$ as completion of $H^1_0(\Omega)$ with respect to the mesh dependent norm

$$\|u\|_{H^2_\rho} := \left(\int_{-1}^1 |u|^2 dx + \sum_{j=1}^{N-1} \rho_j |u(x_j)|^2\right)^{1/2} \quad (2.3)$$
The space $H^0_T$ thus obtained is a Hilbert space and is isomorphic to $L^2(\Omega) \oplus \mathbb{R}^{N-1}$ so that every $u \in H^0_T$ is of the form $u = (\tilde{u}, d_1, d_2, \ldots, d_{N-1})$ and

$$
\|u\|_{H^0_T} = \left( \|\tilde{u}\|_{L^2}^2 + \sum_{j=1}^{N-1} \rho_j |d_j|^2 \right)^{1/2}.
$$

(2.4)

If $u \in H^0_T \cap H^1$ then $\tilde{u} \in H^1$ and $d_j = \tilde{u}(x_j)$. If $u \in L^2(\Omega)$ is discontinuous at the nodes $x_j$ but piecewise smooth, then $\tilde{u} = u$ and $d_j = (u(x_j^+) + u(x_j^-))/2$ where $u(x_j^\pm)$ denotes the left and right limits of $u$ at $x_j$.

Next, we introduce the test space

$$
H^2_T := \{ v \in H^1_0(\Omega) : v|_{I_j} \in H^2(I_j), j = 1, \ldots, N, \}
$$

(2.5)

On the pair $H^0_T \times H^2_T$ we define the bilinear form $B_T(\cdot, \cdot)$ by

$$
B_T(u, v) := \sum_{j=1}^N \int_{I_j} \tilde{u} L^* v \, dx - \sum_{j=1}^{N-1} d_j \left[ \varepsilon v'(x_j) \right]
$$

(2.6)

where $[\varepsilon v'(x_j)]$ denotes the jump of $v'$ at $x_j \in T$. We equip the space $H^2_T$ with the norm

$$
\|v\|_{H^2_T} := \left( \sum_{j=1}^N \|L^*_j v\|_{L^2(I_j)}^2 + \sum_{j=1}^{N-1} \left[ \varepsilon v'(x_j) \right]^2 \rho_j \right)^{1/2}.
$$

(2.7)

We remark in passing that so far we have used $a(x) \in C^0([-1, 1]) \cap C^1(I_j)$, $j = 1, \ldots, N$, rather than $a \in C^1[-1, 1]$. With these definitions we have

**Proposition 2.1** For any mesh $T$ and any positive sequence $\{\rho_j\}_{j=1}^{N-1}$, the bilinear form $B_T(\cdot, \cdot)$ satisfies

$$
|B_T(u, v)| \leq \|u\|_{H^0_T} \|v\|_{H^2_T} \quad \forall u \in H^0_T, v \in H^2_T,
$$

(2.8)

$$
\inf_{0 \neq v \in H^2_T} \sup_{0 \neq u \in H^0_T} \frac{B_T(u, v)}{\|u\|_{H^0_T} \|v\|_{H^2_T}} \geq 1,
$$

(2.9)

and

$$
\forall 0 \neq u \in H^0_T : \sup_{v \in H^2_T} B_T(u, v) > 0.
$$

(2.10)

**Proof:** The bound (2.8) follows directly from the definition of the norms and the Schwarz inequality.

To show (2.9), for given $v \in H^2_T$, we select $u_v = (\tilde{u}, d_1, \ldots, d_{N-1}) \in H^0_T$ as follows:

$$
\tilde{u}|_{I_j} = \text{sgn}(L^*_j v|_{I_j}) \left| L^*_j v|_{I_j} \right|, \quad j = 1, \ldots, N,
$$

$$
d_j = -\rho_j^{-1} |v'(x_j)|, \quad j = 1, \ldots, N - 1.
$$

Then $\|u_v\|_{H^0_T} \leq \|v\|_{H^2_T}$ and $B_T(u_v, v) = \|v\|_{H^2_T}^2$, whence for every $0 \neq v \in H^2_T$

$$
\sup_{0 \neq u \in H^0_T} \frac{B_T(u, v)}{\|u\|_{H^0_T} \|v\|_{H^2_T}} \geq \frac{B_T(u_v, v)}{\|u_v\|_{H^0_T} \|v\|_{H^2_T}} \geq \frac{B_T(u_v, v)}{\|v\|_{H^2_T}^2} = 1
$$

(2.10)
which proves (2.9) and (2.10).

Proposition 2.1 allows us to prove the existence of a solution \( u \in H^0_T \) of the problem:

\[
u \in H^0_T \quad B_T(u, v) = F(v) \quad \forall v \in H^2_T.
\] (2.11)

**Proposition 2.2** Under the assumption (1.3), for every \( f \in L^1(\Omega) \), every \( 0 < \varepsilon \leq 1 \), and every mesh \( T \) and every positive sequence \( \{\rho_j\}_{j=1}^{N-1} \), the problem (2.11) admits a unique solution \( u \in H^0_T \).

**Proof:** We proceed in two steps.

Step i) We claim that for any mesh \( T \), any positive sequence \( \{\rho_j\}_{j=1}^{N-1} \) and any \( \varepsilon \in (0, 1] \), assumptions (1.3) imply

\[
\|v\|_{L^\infty(\Omega)} \leq C_1 \max\{1, \sqrt{\rho}\} \|v\|_{H^2_T},
\] (2.12)

where \( C_1 \) is independent of \( \varepsilon \) and \( T \). To prove it, we note that (1.3) implies the existence of a Green’s function \( G(x, y) \) for the problem (1.1), (1.2) which is bounded uniformly with respect to \( x, y, \varepsilon \) (see [18], Theorem 2.7), i.e.

\[
\max_{(x, y) \in [-1,1]^2} |G(x, y)| \leq C_G.
\]

For \( v \in H^2_T \), we can write

\[
v(y) = \sum_{j=1}^N \int_{I_j} G(x, y)(L^*_\varepsilon v)(x)dx - \sum_{j=1}^{N-1} [\varepsilon v'(x_j)] G(x_j, y), \quad \forall y \in [-1, 1].
\]

Using the boundedness of \( G(x, y) \), we estimate then

\[
|v(y)| \leq C_G \left\{ \sum_{j=1}^N \int_{I_j} |L^*_\varepsilon v| dx + \sum_{j=1}^{N-1} [\varepsilon v'(x_j)] \rho_j^{1/2} \rho_j^{1/2} \right\} \\
\leq \sqrt{2}C_G \max\{\sqrt{2}, \sqrt{\rho}\} \|v\|_{H^2_T}
\]

which proves (2.12).

Step ii) For \( f \in L^1(\Omega) \) and \( v \in H^2_T \), we therefore have

\[
|F(v)| \leq \|f\|_{L^1(\Omega)} \|v\|_{L^\infty(\Omega)} \leq C_1 \max\{1, \sqrt{\rho}\} \|f\|_{L^1(\Omega)} \|v\|_{H^2_T}.
\]

Hence, \( F(\cdot) \) is a continuous, linear functional on \( H^2_T \) the norm of which is bounded uniformly with respect to \( \varepsilon \) and \( T \). By Propositions 2.1 and A.2, we have also

\[
\inf_{0 \neq u \in H^0_T} \sup_{0 \neq v \in H^2_T} \frac{B_T(u, v)}{\|u\|_{H^0_T} \|v\|_{H^2_T}} \geq 1,
\]

\[
\forall 0 \neq v \in H^2_T : \quad \sup_{u \in H^0_T} B_T(u, v) > 0.
\]
This implies with \( F \in (H^2_f)' \) and Proposition A.1 that (2.11) admits a unique solution and that the a-priori estimate
\[
\|u\|_{H^0_f} \leq C_1 \max\{1, \sqrt{\rho}\} \|f\|_{L^1(\Omega)} \tag{2.13}
\]
holds.

\[\square\]

**Remark 2.3** In Step ii) of the proof of Proposition 2.2, we exploit the fact that the embedding \( H^1_f \subset H^0_0(\Omega) \subset C(\Omega) \) is continuous. Hence, the right hand side functional \( F \) may actually be represented by an \( L^1 \) function \( f \) plus a (finite) number of Dirac distributions.

The variational formulation (2.11) is the basis of the FE-discretization.

### 3 \( hp \) Finite Element Discretization

#### 3.1 The Finite Element spaces

We associate with each element \( I_j \) a polynomial degree \( p_j \geq 1 \) and combine the \( p_j \) in the degree-vector \( \vec{p} \). We also set \( p := \max\{p_j : 1 \leq j \leq N\} \). The trial spaces \( S^p_{0,\text{ref}}(\mathcal{T}) \) of our finite element method are the usual spaces of continuous, piecewise polynomials of degree \( p_j \) satisfying the homogeneous boundary conditions (2.1) at \( \pm 1\):

\[
S^p_{0,\text{ref}}(\mathcal{T}) := \left\{ u \in H^p(\Omega) : u|_{I_j} \in \Pi_{p_j}(I_j), j = 1, \ldots, N \right\}, \quad \ell = 1, 2, \ldots \tag{3.1}
\]

If \( \ell = 1 \), we simply write \( S^p_{0}(\mathcal{T}) \).

As test space we choose, following [19], the space of \( L \)-splines of degree \( \vec{p} \) defined by

\[
S^p_{\ell}(\mathcal{T}) := \left\{ v \in H^1_0(\Omega) : (L^*_\ell v)|_{I_j} = 0 \text{ if } p_j = 1, \quad (L^*_\ell v)|_{I_j} \in \Pi_{p_j-2}(I_j) \text{ if } p_j \geq 2 \right\}. \tag{3.2}
\]

Note that (1.3), (1.4) imply that \( L^*_\ell \) and \( L^*_\ell \) are injective. Hence (3.2) makes sense and the test functions belong to \( H^2(I_j), j = 1, \ldots, N \). We omit the argument \( \mathcal{T} \) when it is clear from the context which mesh is meant. Note that, due to (2.2), the space \( S^p_{\ell} \) is well-defined even if the coefficient \( a(x) \) is only piecewise \( C^1 \). We also observe that

\[
M = \dim(S^p_{0}) = -1 + \sum_{j=1}^{N} p_j = \dim(S^p_{\ell}). \tag{3.3}
\]

The finite element approximation \( u_M \) is then obtained in the usual way:

\[
u_M \in S^p_{0}, \quad B_T(u_M, v) = F(v) \quad \forall v \in S^p_{\ell}. \tag{3.4}\]

Due to (3.3), problem (3.4) amounts to solving a linear system of \( M \) equations for the \( M \) unknown coefficients of \( u_M \).
3.2 Stability

Our main result in this section is

**Theorem 3.1** Select

\[
\rho_j := \frac{(h_j + h_{j+1})}{2}, \quad j = 1, \ldots, N - 1. \tag{3.5}
\]

Then for all \(0 < \varepsilon \leq 1\), \(T\) and \(\bar{p}\) there holds

\[
\inf_{0 \neq v \in S_L^0} \sup_{0 \neq u \in S_\bar{p}^0} \frac{B_T(u, v)}{\|u\|_{H_T^\rho} \|v\|_{H_T^\rho}} \geq \frac{1}{\gamma_M} \tag{3.6}
\]

with \(\gamma_M = \max\{\sqrt{5}, \sqrt{p + 3}\}\).

**Proof:** We show that for every \(v \in S_L^0\) there exists \(u_v \in S_\bar{p}^0\) such that

\[
B_T(u_v, v) \geq \|v\|_{H_T^\rho}^2, \quad \|u_v\|_{H_T^\rho} \leq \gamma_M \|v\|_{H_T^\rho}.
\]

To this end, we write

\[
u_v|_{I_j} = \sum_{i=0}^{p_j} a_{ij} L_i \left(2 \frac{x - m_j}{h_j}\right), \tag{3.7}
\]

where \(L_i\) denotes the \(i\)th Legendre polynomial on \((-1, 1)\) normalized such that \(L_i(1) = 1\).

A basis for \(S_L^0\) can be obtained as follows: First, we define external, nodal upwinded shape functions \(\psi_{-1,j} \in H_0^1(T_{j-1} \cup T_j)\) by

\[
\begin{align*}
L^*_e \psi_{-1,j} &= 0 \text{ in } I_{j-1} \cup I_j, j = 2, \ldots, N, \\
\psi_{-1,j}(x_k) &= \delta_{j,k+1}, k = 1, \ldots, N, \\
\psi_{-1,j} &= 0 \text{ elsewhere.}
\end{align*} \tag{3.8}
\]

Note that \(\psi_{-1,j} \in H^2(I_j), j = 1, \ldots, N\). The nodal shape functions \(\psi_{-1,j}\) are augmented for \(p_j \geq 2\) by internal, upwinded shape functions \(\psi_{i,j} \in (H^2 \cap H_0^1)(I_j)\). They are defined by

\[
\begin{align*}
L^*_e \psi_{i,j} &= L_i \left(2 \frac{x - m_j}{h_j}\right) \text{ in } I_j, i = 0, \ldots, p_j - 2, j = 1, \ldots, N \\
\psi_{i,j} &= 0 \text{ elsewhere.}
\end{align*} \tag{3.9}
\]

Any \(v \in S_L^0\) can be written as

\[
v(x) = \sum_{j=2}^{N} v(x_{j-1}) \psi_{-1,j}(x) + \sum_{j=1}^{N} \sum_{i=0}^{p_j-2} b_{ij} \psi_{i,j}(x) \tag{3.10}
\]

where \(b_{ij}\) are the Legendre coefficients of \(L^*_e v|_{I_j}\). Further, from the definition (3.8) of the \(\psi_{-1,j}\) we have

\[
L^*_e v|_{I_j} = \sum_{i=0}^{p_j-2} b_{ij} L_i \left(2 \frac{x - m_j}{h_j}\right), \quad j = 1, \ldots, N
\]
which yields with the orthogonality properties of the Legendre polynomials and a scaling argument
\[
\sum_{j=1}^{N} \| L_j^* v \|_{L^2(I_j)}^2 = \sum_{j=1}^{N} h_j \sum_{i=0}^{p_j-2} \frac{|b_{ij}|^2}{2i+1} =: \sum_{j=1}^{N} h_j S_j. \tag{3.11}
\]
Combining (3.11) with (2.7), we obtain for \( v \in S_L^p \) an expression for \( \| v \|_{H^2_T} \) in terms of the \( b_{ij} \):
\[
\| v \|_{H^2_T} = \left( \sum_{j=1}^{N} h_j \sum_{i=0}^{p_j-2} \frac{|b_{ij}|^2}{2i+1} + \sum_{j=1}^{N-1} \frac{\| \varepsilon v' (x_j) \|_2^2}{\rho_j} \right)^{1/2} \quad \forall v \in S_L^p. \tag{3.12}
\]
Writing \( v(x) \) in the form (3.10) and \( u_v(x) \) as in (3.7) and inserting into (2.6), we find in the same way
\[
B_T(u_v, v) = \sum_{j=1}^{N-1} \left\{ h_j \sum_{i=0}^{p_j-2} \frac{a_{ij} b_{ij}}{2i+1} - \sum_{j=1}^{N-1} u_v(x_j) \left[ \varepsilon v'(x_j) \right] \right\}. \tag{3.13}
\]
For given \( v \in S_L^p \), i.e. for given \( b_{ij} \), we choose now \( a_{ij} \) as follows: first, we select
\[
a_{ij} = b_{ij} \quad i = 0, ..., p_j - 2 \tag{3.14}
\]
which leaves \( a_{p_j-1,j}, a_{p_j,j} \) to be determined, for each \( I_j \). Since \( u_v \) must be continuous, two conditions per interval must be enforced. We prescribe \( u_v \) at each endpoint of \( I_j \) as follows (by \( u_v(x^\pm) \) we denote the right/left limit of \( u_v \) at \( x \)):
\[
u_v(x^+_{j-1}) = a_j^- := \begin{cases} 0 & \text{if } j > 1, \\ -[\varepsilon v'(x_{j-1})] / \rho_{j-1} & \text{if } j = 1 \end{cases} \tag{3.15}
\]
and
\[
u_v(x^-_j) = a_j^+ := \begin{cases} 0 & \text{if } j < N, \\ -[\varepsilon v'(x_j)] / \rho_j & \text{if } j = N. \end{cases} \tag{3.16}
\]
Conditions (3.15), (3.16) ensure continuity of \( u_v \). Since \( L_i (\pm 1) = (\pm 1)^i \) implies
\[
u_v(x^+_{j-1}) = \sum_{i=0}^{p_j} (-1)^i a_{ij}, \quad \nu_v(x^-_j) = \sum_{i=0}^{p_j} (-1)^i a_{ij}
\]
we get with (3.14) the linear system
\[
\begin{bmatrix}
(-1)^{p_j-1} & (-1)^p_j \\
1 & 1
\end{bmatrix}
\begin{bmatrix}
\begin{bmatrix}
a_{p_j-1,j}^- \\
-1
\end{bmatrix} \\
\begin{bmatrix}
a_{p_j,j}^- \\
-1
\end{bmatrix}
\end{bmatrix} = \begin{bmatrix}
a_j^- - \sum_{i=0}^{p_j-2} (-1)^i b_{ij} \\
a_j^+ - \sum_{i=0}^{p_j-2} b_{ij}
\end{bmatrix}. \tag{3.17}
\]
Its determinant is nonzero for any \( p_j \), therefore \( u_v \) is uniquely determined by (3.14) and (3.17).

From (3.13), (3.14) and (3.15), (3.16) we get
\[
B_T(u_v, v) = \| v \|_{H^2_T}^2.
\]
It remains therefore to show
\[ \|u_0\|_{H^2_{\rho}} \leq \gamma_M \|v\|_{H^2_{\rho}} \] (3.18)
with \( \gamma_M \) as in (3.6).
Since \( u_0 \) is continuous, we have
\[
\|u_0\|_{H^2_{\rho}}^2 = \sum_{j=1}^{N} \|u_0\|_{L^2(t_j)}^2 + \rho_j \|u_0(x_j)\|^2
\]
\[
= \sum_{j=1}^{N} h_j \sum_{i=0}^{\rho_j} \frac{|a_{ij}|^2}{2i+1} + \rho_j \|u_0(x_j)\|^2
\]
\[
= \sum_{j=1}^{N} \left\{ h_j \sum_{i=0}^{\rho_j} \frac{|b_{ij}|^2}{2i+1} + h_j \sum_{i=0}^{\rho_j} \frac{|a_{ij}|^2}{2i+1} \right\} + \rho_j^{-1} \|v'(x_j)\|^2
\]
\[
= \|v\|_{H^2_{\rho}}^2 + \sum_{j=1}^{N} h_j \sum_{i=0}^{\rho_j} \frac{|a_{ij}|^2}{2i+1}.
\] (3.19)

We estimate \( |a_{ij}|^2 \) for \( i = p_j - 1, p_j \). From (3.17), we get
\[
\begin{bmatrix}
  a_{p_j-1,j} \\
  a_{p_j,j}
\end{bmatrix} = \frac{1}{2(-1)^{p_j}} \begin{bmatrix}
  1 \quad (-1)^{p_j-1} \\
  -1 \quad (-1)^{p_j-1}
\end{bmatrix} \begin{bmatrix}
  a_j^- - \sum_{i=0}^{p_j-2} (-1)^i b_{ij} \\
  a_j^+ - \sum_{i=0}^{p_j-2} b_{ij}
\end{bmatrix}
\]
\[
= \frac{1}{2(-1)^{p_j}} \begin{bmatrix}
  a_j^- + (-1)^{p_j-1} a_j^+ + \sum_{i=0}^{p_j-2} b_{ij}((-1)^{p_j} - (-1)^i) \\
  -a_j^- + (-1)^{p_j-1} a_j^+ + \sum_{i=0}^{p_j-2} b_{ij}((-1)^i + (-1)^{p_j})
\end{bmatrix}.
\]

We estimate
\[
\max\{|a_{ij}| : i = p_j - 1, p_j\} \leq \frac{1}{2} \left( |a_j^-| + |a_j^+| \right) + \sum_{i=0}^{p_j-2} |b_{ij}|
\]
and get with (3.15), (3.16) that
\[
\max\{|a_{ij}|^2 : i = p_j - 1, p_j\} \leq \varepsilon^2 \left( \frac{\|v'(x_{j-1})\|^2}{\rho_j^2} + \frac{\|v'(x_j)\|^2}{\rho_j^2} \right) + 2 \left( \sum_{i=0}^{p_j-2} |b_{ij}| \right)^2.
\]

With the understanding that \( [v'(x_0)] = [v'(x_N)] = 0 \) and \( \rho_0 = \rho_N = \infty \) we estimate further
\[
\sum_{j=1}^{N} h_j \sum_{i=p_j-1}^{\rho_j} \frac{|a_{ij}|^2}{2i+1}
\]
\[
\leq \sum_{j=1}^{N} \frac{h_j}{2p_j - 1} \left\{ \frac{\|v'(x_{j-1})\|^2}{\rho_j^2} + \frac{\|v'(x_j)\|^2}{\rho_j^2} + 2 \left( \sum_{i=0}^{p_j-2} |b_{ij}| \right)^2 \right\}
\]
\[
\leq \sum_{j=1}^{N} \frac{h_j}{2p_j - 1} \left\{ \frac{\|v'(x_{j-1})\|^2}{\rho_j^2} + \frac{\|v'(x_j)\|^2}{\rho_j^2} + 2 \sum_{i=0}^{p_j-2} (2i+1) \sum_{i=0}^{p_j-2} |b_{ij}|^2 \right\}
\]
\[
= \sum_{j=1}^{N} \frac{h_j}{2p_j - 1} \left\{ \frac{\|v'(x_{j-1})\|^2}{\rho_j^2} + \frac{\|v'(x_j)\|^2}{\rho_j^2} + 2(p_j - 1)^2 \sum_{i=0}^{p_j-2} |b_{ij}|^2 \right\}.
\]
Now using $h_j/\rho_j \leq 2$, $h_j/\rho_{j-1} \leq 2$ and
\[
\max\{\frac{2(p_j - 1)^2}{2p_j - 1} : j = 1, \ldots, N\} \leq p + 2
\]
we arrive at
\[
\sum_{j=1}^{N} h_j \sum_{i=p_j-1}^{p_j} \frac{|a_{ij}|^2}{2i+1} \leq 4 \sum_{j=1}^{N-1} \frac{[\varepsilon v'(x_j)]^2}{\rho_j} + (p + 2) \sum_{j=1}^{N} h_j \sum_{i=0}^{p_j-2} \frac{|b_{ij}|^2}{2i+1}
\]
\[
\leq \max\{4, p + 2\} \|v\|_{H^2_T}^2
\]
where we used (2.7) and (3.11). Referring to (3.19) completes the proof.

\[\square\]

**Remark 3.2** In Theorem 3.1, we selected a specific sequence $\{\rho_j\}$. Inspection of the proof shows that any positive sequence is admissible. Then, however,
\[
\gamma_M \geq C \sqrt{p} \max_{1 \leq j \leq N} \{h_j/\rho_j, h_j/\rho_{j-1}\}. \tag{3.20}
\]
This shows that in order for $\gamma_M$ to be independent of $T$, the weights $\rho_j$ must essentially be of the order of the local meshwidth.

### 3.3 Consistency and Convergence

Theorem 3.1 implies with Proposition A.4 and (2.8), (2.9) that
\[
\inf_{0 \neq u \in \mathcal{S}_0^\rho} \sup_{0 \neq v \in \mathcal{S}_L^\rho} \frac{B_T(u, v)}{\|u\|_{H^2_T} \|v\|_{H^2_T}} \geq \frac{1}{\gamma_M}, \tag{3.21}
\]
\[
\forall 0 \neq v \in \mathcal{S}_L^\rho : \sup_{u \in \mathcal{S}_0^\rho} B(u, v) > 0. \tag{3.22}
\]
Referring to (2.10), we deduce from (3.21) and from Proposition A.3 that for every mesh-degree combination $(\bar{p}, T)$ there exists a unique FE-solution $u_M$ of (3.4). In particular, the $M \times M$ (generally nonsymmetric) stiffness matrix corresponding to (3.4) is nonsingular. Moreover, the FE-solution $u_M$ is quasi-optimal, i.e.
\[
\|u - u_M\|_{H^2_T} \leq (1 + \gamma_M) \|u - w\|_{H^2_T} \quad \forall w \in \mathcal{S}_0^\rho. \tag{3.23}
\]
The rate of convergence of the FEM (3.4) is therefore determined by the approximability of the exact solution $u$ from the trial space $\mathcal{S}_0^\rho$. We show that proper selection of the mesh $T$ and of the polynomial degree distribution $\bar{p}$ yields an exponential rate of convergence, uniform in $\varepsilon$. We will consider the approximation of two types of solutions $u_\varepsilon$. In Section 3.3.1, we consider the case of analytic right hand sides $f$. In that case, the solution $u_\varepsilon$ exhibits only a boundary layer at the outflow boundary and thus a “two-element” mesh with one small element in the outflow boundary layer. In Section 3.3.2, we analyze the approximation of solutions stemming from right hand sides that contain Dirac distributions (Note that such right hand sides are admissible by Remark 2.3). Such solutions exhibit internal layers and in the limit (as $\varepsilon \to 0$) such solutions correspond to shocks. We show in Section 3.3.2 that the addition of a small element in each resolves these smeared-out shocks robustly.
3.3.1 Approximation of boundary layers

**Theorem 3.3** Let \( u_\varepsilon \) be the solution of (1.1), (2.1), and assume that the coefficients \( a, b \) and the right hand side \( f \) satisfy (1.3), (1.5)–(1.7). For every \( \varepsilon, \kappa > 0 \) let the degree vector \( \vec{p} \) and the mesh \( T = T_{\kappa, \varepsilon} \) be given by

\[
\vec{p} = \{p, p\}, \quad T_{\kappa, \varepsilon} = \{I_1, I_2\} \quad \text{if } \kappa \varepsilon < 1,
\]

\[
\vec{p} = \{p\}, \quad T_{\kappa, \varepsilon} = \{\Omega\} \quad \text{if } \kappa \varepsilon \geq 1.
\]

where

\[
I_1 = (-1, 1 - \kappa \varepsilon), \quad I_2 = (1 - \kappa \varepsilon, 1).
\]

Then there is a constant \( \kappa_0 \) depending only on the constants of (1.3), (1.5)–(1.7) such that for every \( 0 < \kappa < \kappa_0 \) there are \( C, \sigma > 0 \) independent of \( \varepsilon \) and \( p \) such that

\[
\inf_{v_p \in S_p^{\kappa, \varepsilon}(T_{\kappa, \varepsilon})} \|u_\varepsilon - v_p\|_{L^\infty(\Omega)} \leq C \varepsilon^{-\sigma} \quad \forall p \in \mathbb{N}.
\]

Let us comment on Theorem 3.3 before proving it. As \( \|u_\varepsilon - v_p\|^2_{H^1_0} \leq 3\|u_\varepsilon - v_p\|^2_{L^\infty(\Omega)} \), Theorem 3.3 shows with (3.23) that for analytic input data robust exponential convergence can be achieved by the FE scheme (3.4) provided the space \( S_p^{\kappa, \varepsilon} \) is designed properly (i.e. with one element of size \( O(\varepsilon) \) in the outflow boundary layer) and provided that the corresponding stable test space \( S_p^{\kappa, \varepsilon}(T) \) is available. Results analogous to Theorem 3.3 hold also true when \( f(x) \) is piecewise analytic on \([-1, 1]\); then, however, additional internal layers arise at points of nonanalyticity of \( f \) which must be accounted for by adding further \( O(\varepsilon^{p+1}) \) elements.

**Remark 3.4** An estimate on the value of the constant \( \kappa_0 \) is in principle available from the proof of Theorem 3.3. For constant coefficients \( a, b \), the value of \( \kappa_0 \) can be determined explicitly ([15]): \( \kappa_0 = 4/(\varepsilon \lambda) \) where \( \lambda = (a + \sqrt{a^2 + 4\varepsilon^2})/2 \geq a/2 \) by assumption (1.3). The numerical experiments of [15] show moreover, that the approximation properties of piecewise polynomials on the meshes \( T_{\kappa, \varepsilon} \) are fairly insensitive to the precise choice of \( \kappa \).

In order to prove Theorem 3.3, we need two lemmas on the approximation of analytic functions by their Gauss-Lobatto interpolants. Let \( I = [-1, 1] \) and define on \( C(I) \) interpolation operator \( i_p \), by interpolation in the \( p + 1 \) Gauss-Lobatto points. By [17] we have the following stability result

\[
\|i_p u\|_{L^\infty(I)} \leq C_{GL}(1 + \ln p)\|u\|_{L^\infty(I)} \quad \forall u \in C(I), \quad p \in \mathbb{N}.
\]

A direct consequence of this stability estimate and Markov’s inequality, \( \|v_p'\|_{L^\infty(I)} \leq p^2 \|v_p\|_{L^\infty(I)} \), valid for all polynomials \( v_p \) of degree \( p \), is the following

**Lemma 3.5** Let \( u \in C^2(I) \). Then

\[
\| (u - i_p u)_{[l]} \|_{L^\infty(I)} \leq \|u_{[l]}\|_{L^\infty(I)} + C_{GL}(1 + \ln p)p^{2l}\|u\|_{L^\infty(I)}, \quad l = 0, 1, 2.
\]

For analytic functions \( u \), we have
Lemma 3.6 Let \( u \in C^\infty(I) \) satisfy
\[
\|u^{(n)}\|_{L^\infty(I)} \leq C_n \gamma^n n! \quad \forall n \in \mathbb{N}_0.
\]
Then there are constants \( C, \sigma > 0 \) depending only on \( C_{GL} \) and \( \gamma \) such that
\[
\left\| u - i_p u \right\|_{L^\infty(I)} + \left\| (u - i_p u)' \right\|_{L^\infty(I)} + \left\| (u - i_p u)'' \right\|_{L^\infty(I)} \leq CC_n e^{-\sigma p} \quad \forall p \in \mathbb{N}.
\]
Proof: The growth estimates on the derivatives of \( u \) imply that \( u \) is analytic on the closed set \( I \). By standard theory, there are polynomials \( P_p \) of degree \( p \) (e.g., by interpolating \( u \) in the Tschebyscheff points; cf. [3], Chap. 4 for the details) such that
\[
\left\| u - P_p \right\|_{L^\infty(I)} + \left\| (u - P_p)' \right\|_{L^\infty(I)} + \left\| (u - P_p)'' \right\|_{L^\infty(I)} \leq CC_n e^{-\sigma p} \quad \forall p \in \mathbb{N}
\]
for some \( C, \sigma > 0 \) depending only on \( \gamma \). As the interpolation operator \( i_p \) reproduces polynomials, we have \( u - i_p u = (u - P_p) - i_p(u - P_p) \) and the desired result follows from an application of Lemma 3.5 to \( u - P_p \).

Proof of Theorem 3.3: We will choose the approximant \( v_p \) as the (piecewise) Gauss-Lobatto interpolant of \( u \). Because the endpoints of the elements are sampling points of the Gauss-Lobatto interpolation operator and because \( u(\pm 1) = 0 \), the piecewise Gauss-Lobatto interpolant is in \( S_{1}^{\kappa,1}(T_{\kappa,\varepsilon}) \), and we merely have to control the approximation error on the sub-intervals.

Let us first consider the asymptotic case, i.e., \( \kappa \varepsilon \geq 1 \). By Theorem 1.1, we have
\[
\left\| u^{(n)}_\varepsilon \right\|_{L^\infty(\Omega)} \leq CK^n \max(n, \varepsilon^{-1})^n \quad \forall n \in \mathbb{N}_0.
\]
Furthermore, we have by Stirling's formula the existence of \( C > 0 \) such that
\[
\max(n, \varepsilon^{-1})^n \leq \max(n^n, n!e^{-n}/n!) \leq \max(n^n, n!e^{1/\varepsilon}) \leq Cn!e^{n/e^{1/\varepsilon}}.
\]
Lemma 3.6 allows us to conclude that there are \( C, \sigma > 0 \) independent of \( p, \varepsilon \) such that
\[
\left\| u_\varepsilon - i_p u_\varepsilon \right\|_{L^\infty(\Omega)} \leq Ce^{1/\kappa} e^{-\sigma p}.
\]
The assumption \( \kappa \varepsilon \geq 1 \) implies \( e^{1/\kappa} \leq e^{\sigma p} \) and thus the claim of the theorem follows in the asymptotic regime provided that \( 0 < \kappa < \kappa_0 \leq \sigma \).

In the pre-asymptotic case \( \kappa \varepsilon < 1 \), we use the decomposition (1.8) with expansion order \( M \) given by
\[
M = \mu \kappa p \quad \text{with } \mu \text{ such that } \mu K =: \beta < 1
\]
where \( K > 0 \) is the constant of Theorem 1.1 (strictly speaking, we should take \( M \) as the integer part of \( \mu \kappa p \)— for notational convenience, however, we will ignore this point henceforth). This choice of \( \mu \) guarantees that the statements of Theorem 1.1 on the terms of the decomposition (1.8) hold true because \( \kappa \varepsilon \leq 1 \). Denote by \( l_1 \) and \( l_2 \) the two linear maps which map the reference interval \( I \) onto the physical elements \( I_1, I_2 \), and define, for \( u \in C[-1, 1] \), the piecewise Gauss-Lobatto interpolant \( \pi_p(u) \in S_{1}^{\kappa,1}(T_{\kappa,\varepsilon}) \) of \( u \) by
\[
\pi_p(u)|_{I_i} = i_p(u \circ l_i) \circ l_i^{-1}.
\]
Let us now consider the difference between the terms of the decomposition (1.8) and their Gauss-Lobatto interpolants.

First, let us analyze the term \( w_M \). As the maps \( l_i \) are linear with \( |l_i'| \leq 1, i = 1, 2 \), Theorem 1.1 allows us to infer that the functions \( w_M \circ l_i \) defined on the reference element \( I \) satisfy the derivative growth estimates

\[
\| (w_M \circ l_i)^{(n)} \|_{L^\infty(I)} \leq C K^n n! \quad \forall n \in \mathbb{N}_0
\]

with \( C, K \) given by Theorem 1.1. Thus, by Lemma 3.6 there are \( C, \sigma > 0 \) such that

\[
\| w_M \circ l_i - i_p (w_M \circ l_i) \|_{L^\infty(I)} \leq C e^{-\sigma p} \quad \forall p \in \mathbb{N}, \quad i = 1, 2
\]

from whence we immediately get that

\[
\| w_M - \pi_p (w_M) \|_{L^\infty(\Omega)} \leq C e^{-\sigma p}.
\]

Consider now the approximation of \( C_M u^+_2 \) on the small boundary layer element \( I_2 \). First, observe that \( C_M \leq C \) independently of \( M, \varepsilon \) by our choice of \( \mu \). With the aid of Theorem 1.1, the fact that \( l_2' = \kappa \varepsilon / 2 \), and the assumption \( \kappa \varepsilon \leq 1 \), we obtain

\[
\| (u^+_2 \circ l_2)^{(n)} \|_{L^\infty(I)} \leq C K^n (\kappa \varepsilon / 2)^n \max(n, \varepsilon^{-1})^n \leq C(K/2)^n \max(\kappa \varepsilon n, \kappa p)^n \leq C(K/2)^n \max(n^n, n!(\kappa p)^n/n!) \leq C(K/2)^n e^{n^\sigma}. \]

Hence, Lemma 3.6 allows us to conclude the existence of \( C, \sigma > 0 \) independent of \( \varepsilon, p \) such that

\[
\| u^+_2 \circ l_2 - i_p (u^+_2 \circ l_2) \|_{L^\infty(\Omega)} \leq C e^{\sigma p} e^{-\sigma p}. \tag{3.30}
\]

This term is exponentially small provided that \( \kappa < \kappa_0 \leq \sigma \). Let us now turn our attention to the approximation of \( C_M u^+_2 \) on \( I_1 \). By Theorem 1.1, we have that

\[
\| u^+_2 \circ l_1 \|_{L^\infty(I)} \leq C e^{-\kappa p / 2}. \tag{3.31}
\]

Thus, by Lemma 3.5

\[
\| u^+_2 \circ l_1 - i_p (u^+_2 \circ l_1) \|_{L^\infty(I)} \leq C e^{-\sigma p} \tag{3.31}
\]

for some properly chosen \( \sigma > 0 \). Combining (3.30), (3.31) allows us to conclude that

\[
\| C_M u^+_2 - \pi_p (C_M u^+_2) \|_{L^\infty(\Omega)} \leq C e^{-\sigma p}
\]

for appropriate \( \sigma > 0 \). Finally, for the remainder, Theorem 1.1 yields with our choice of \( \mu \)

\[
\| r_M \|_{L^\infty(\Omega)} \leq C \varepsilon (\varepsilon \mu \kappa K)^M \leq C \varepsilon (\varepsilon M K)^M \leq C \beta^{\mu \sigma \varepsilon} \tag{3.32}
\]

with \( \beta < 1 \). Thus, the remainder \( r_M \) is exponentially small on \( \Omega \), and an appropriate application of Lemma 3.5 allows us to conclude the proof of Theorem 3.3 by observing that

\[
\| r_M - \pi_p (r_M) \|_{L^\infty(\Omega)} \leq C \beta^{\mu \sigma \varepsilon} = C e^{-\sigma p}, \quad \sigma = \mu \kappa |\ln \beta|.
\]

\( \square \)
3.3.2 Approximation of shocks

In this section, we want to demonstrate that the ideas of the “two-element” mesh of the preceding section can be used for the approximation of solutions $u_\varepsilon$ which are smeared-out shocks. To that end, let us consider

$$L_\varepsilon u_\varepsilon = f + \delta_0 \quad \text{on } \Omega, \quad u_\varepsilon(\pm 1) = \alpha^\pm$$  \hspace{1cm} (3.33)

where $\delta_0$ denotes the Dirac distribution concentrated at the point $x = 0$. The following analog of Theorem 3.3 holds.

**Theorem 3.7** Let $u_\varepsilon$ be the solution of (3.33) and assume that the coefficients $a$, $b$ and the right hand side $f$ satisfy (1.3), (1.5)-(1.7). For every $\varepsilon$, $\kappa > 0$ let the degree vector $\tilde{p}$ and the “four-element” mesh $\mathcal{T} = \mathcal{T}_{\kappa, \varepsilon}$ be given by

$$\tilde{p} = \{p, p, p, p\}, \quad \mathcal{T} = \{I_1, I_2, I_3, I_4\} \quad \text{if } \kappa \varepsilon < 1/2,$$

$$\tilde{p} = \{p\}, \quad \mathcal{T} = \{\Omega\} \quad \text{if } \kappa \varepsilon \geq 1/2. \hspace{1cm} (3.34)$$

where

$$I_1 = (-1, -\kappa \varepsilon), \quad I_2 = (-\kappa \varepsilon, 0), \quad I_3 = (0, 1 - \kappa \varepsilon), \quad I_4 = (1 - \kappa \varepsilon, 1).$$

Then there is $\varepsilon_0 > 0$ depending only on the constants (1.3), (1.5)-(1.7) such that for every $0 < \varepsilon \leq \varepsilon_0$ the following holds. Then there is a constant $\kappa_0$ also depending only on the constants of (1.3), (1.5)-(1.7) such that for every $0 < \kappa < \kappa_0$ there are $C$, $\sigma > 0$ independent of $p$ and $\varepsilon$ such that

$$\inf_{v_\varepsilon \in \mathcal{S}_0^0(\mathcal{T}_{\kappa, \varepsilon})} \|u_\varepsilon - v_\varepsilon\|_{L^\infty(\Omega)} \leq C e^{-\sigma p} \quad \forall p \in \mathbb{N}.$$  

**Proof:** Let us first define a function $u_\varepsilon$ with the property that $L_\varepsilon u_\varepsilon = \delta_0$. To that end, let us introduce the following two auxiliary functions, $u_L$, $u_R$:

$$L_\varepsilon u_L = 0 \quad \text{on } (-1, 0), \quad u_L(-1) = 0, \quad u_L(0) = 1,$$

$$u_R = e^{-\Lambda(x) + \Lambda(0)} \quad \text{on } (0, 1)$$

where the function $\Lambda$ is defined in (1.8). Note that $u_L(0) = u_R(0)$ and that $u_R$ is smooth and independent of $\varepsilon$. In particular, $u_R'(0) = -\Lambda(0)$ independently of $\varepsilon$. Lemma B.3 gives the existence of $C_1, C_2 > 0$ independent of $\varepsilon$ such that $C_1 \varepsilon^{-1} \leq u_L'(0) \leq C_2 \varepsilon^{-1}$. Defining

$$D_\varepsilon := -\left(\varepsilon u_R'(0) - \varepsilon u_L'(0)\right)$$ \hspace{1cm} (3.35)

we see that there are $C_1', C_2' > 0$ independent of $\varepsilon$ such that

$$0 < C_1' \leq D_\varepsilon \leq C_2' \quad \forall 0 < \varepsilon \leq \varepsilon_0 \hspace{1cm} (3.36)$$

provided that $\varepsilon_0$ sufficiently small. Define now

$$u_\varepsilon := \frac{1}{D_\varepsilon} \begin{cases} u_L(x) & \text{if } -1 \leq x \leq 0 \\ u_R(x) & \text{if } 0 \leq x \leq 1 \end{cases} \hspace{1cm} (3.37)$$
Then \( u_\varepsilon \) is continuous on \( \Omega \), satisfies \( L_\varepsilon u_\varepsilon = 0 \) on \((-1, 0) \cup (0, 1)\), and the jump of \(-\varepsilon u_\varepsilon\) at \( x = 0 \) is 1 by the choice of \( D_\varepsilon \). Thus, \( u_\varepsilon \) satisfies \( L_\varepsilon u_\varepsilon = \delta_0 \) in the sense of distributions. By superposition, the solution \( u_\varepsilon \) of (3.33) can be written as

\[
 u_\varepsilon = u_\xi + \bar{u}_\varepsilon
\]

where \( \bar{u}_\varepsilon \) solves the auxiliary problem

\[
 L_\varepsilon \bar{u}_\varepsilon = f \quad \text{on } \Omega, \quad \bar{u}_\varepsilon(-1) = \alpha^-, \quad \bar{u}_\varepsilon(1) = \alpha^+ - \delta_\varepsilon(1) \tag{3.38}
\]

By Theorem 3.3, the function \( u_L \) can be approximated with the desired exponential accuracy on a two-element mesh on \((-1, 0)\). Such a two-element mesh is contain in the “four-element” mesh consider here. The function \( u_R \) is analytic and independent of \( \varepsilon \) and thus can be approximated well by polynomials on \((0, 1)\). Noting that the factor \( 1/D_\varepsilon \) appearing in the definition of \( u_\varepsilon \) can be bounded uniformly in \( \varepsilon \) (for \( \varepsilon \leq \varepsilon_0 \)) finishes the approximation argument for \( u_\varepsilon \). By this uniform bound on \( 1/D_\varepsilon \) and by the independence of \( u_R \) of \( \varepsilon \), we conclude that \( u_\varepsilon(1) \) can be bounded uniformly in \( \varepsilon \) and thus Theorem 3.3 allows us to approximate \( \bar{u}_\varepsilon \) to the desired accuracy on a two-element mesh for \( \Omega \). Such a two-element mesh is contained in the “four-element mesh” considered here which concludes the proof.

\[\Box\]

4 Approximate test functions

Theorem 3.1 shows that the use of the upwind ed test space \( S_L^p \) in (3.2) gives rise to a stable numerical scheme. Unfortunately, however, the shape functions \( \psi_{k,j} \) in (3.8), (3.9) are themselves solutions of (local) convection-diffusion problems. For the case \( p = 1 \) and constant coefficients \( a, b \), these upwind ed test functions can be computed explicitly and lead to the so-called “Hemker test functions” [7]. For non-constant coefficients, however, they are not explicitly available. We show therefore now that stability can be retained even if the \( \psi_{k,j} \) are known only approximately. The perturbation analysis of Section 4.1 shows that fairly weak accuracy requirements on the test functions \( \psi_{ij} \) suffice to ensure stability of the FEM. Especially for low \( p \) rather “crude” approximations to the \( L \)-splines \( \psi_{ij} \) are sufficient; this is the reason why techniques such as \( \alpha \)-quadratic upwinding ([2]; see also [12] for an up-to-date account on these methods) and the use of Hemker test functions ([5, 6]) obtained by freezing coefficients lead to stable FEM. All these methods are in fact covered by our perturbation analysis.

4.1 Stability with approximate test functions

We introduce the approximate test space

\[
 \tilde{S}_L^p = \text{span} \left\{ \tilde{\psi}_{k,j} : k = -1, j = 2, ..., N \text{ and } k = 0, ..., p_j - 2, j = 1, ..., N \right\} \tag{4.1}
\]
where the approximate test functions $\tilde{\psi}_{k,j} \in H^1_0(\Omega) \cap H^2(I_j), j = 1, \ldots, N$ are assumed to satisfy:

$$L^*_\varepsilon \tilde{\psi}_{-1,j} = \eta_{-1,j} \text{ in } I_{j-1} \cup I_j, j = 2, \ldots, N,$$

$$\tilde{\psi}_{-1,j} = 0 \text{ elsewhere},$$

$$\tilde{\psi}_{-1,j}(x_k) = \delta_{j,k+1}, \quad k = 1, \ldots, N,$$

and

$$L^*_\varepsilon \tilde{\psi}_{i,j} = L_i \left( \frac{x - m_j}{h_j} \right) + \eta_{i,j} \text{ in } I_j, \quad i = 0, \ldots, p_j - 2, \quad j = 1, \ldots, N,$$

$$\tilde{\psi}_{i,j} = 0 \text{ elsewhere.}$$

(4.2)

(4.3)

The question how to obtain such approximate test functions will be addressed below.

We show first that the bilinear form $B_T(\cdot, \cdot)$ is stable on $S^p_0 \times \hat{S}_L^p$ provided the residuals $\eta_{k,j}$ in (4.2), (4.3) are sufficiently small.

**Theorem 4.1** Assume that $\rho_j$ is as in (3.5) and that the approximate test functions $\tilde{\psi}_{k,j}$ satisfy (4.2), (4.3) with $\eta_{k,j}$ such that

$$\Lambda_1 \leq c \min\{ \frac{1}{4C_1}, \gamma^{-4}_M \}, \quad \Lambda_2 \leq c \min\{ \frac{1}{10}, \gamma^{-4}_M \}$$

(4.4)

where $c < 1$,

$$\Lambda_1 := \sum_{j=1}^{N} \| \eta_{-1,j} \|^2_{L^2(I_j)} + \| \eta_{-1,j+1} \|^2_{L^2(I_j)},$$

$$\Lambda_2 := \max_{1 \leq j \leq N} \left\{ h_j^{-1} \sum_{i=0}^{p_j-2} (2i + 1) \| \eta_{ij} \|^2_{L^2(I_j)} \right\}$$

(4.5)

(4.6)

(we set $\Lambda_2 := 0$ if $p = 1$ and $\eta_{-1,1} = \eta_{-1,N+1} = 0$) and $C_1$ is the constant in (2.12).

There exists $C > 0$ independent of $\varepsilon$, $\tilde{\rho}$ and $T$ such that

$$\inf_{0 \neq v \in \hat{S}_L^p} \sup_{0 \neq u \in S_0^p} \frac{B_T(u, v)}{\| u \|_{H^1_0} \| v \|_{H^1_0}} \geq \frac{C}{\gamma_\varepsilon > 0},$$

(4.7)

**Proof:** Let $\tilde{v} \in \hat{S}_L^p$ be given. Then

$$\tilde{v}(x) = \sum_{j=2}^{N} \tilde{v}(x_{j-1}) \tilde{\psi}_{-1,j}(x) + \sum_{j=1}^{N} \sum_{i=0}^{p_j-2} h_j \tilde{\psi}_{ij}(x).$$

We select $u_\varepsilon$ as in the proof of Theorem 3.1, i.e.

$$u_\varepsilon |_{I_j} = \sum_{i=0}^{p_j} a_{ij} L_i \left( \frac{x - m_i}{h_j} \right)$$

where

$$a_{ij} = b_{ij}, \quad i = 0, \ldots, p_j - 2$$
and $a_{p_j-1,j}$, $a_{p_j,j}$ are selected as in (3.15)-(3.17), with $\tilde{v}$ in place of $v$. Then $u_{\tilde{v}}$ is continuous on $[-1,1]$. With the test functions $\psi_{i,j}$ in (3.8), (3.9) we define also

$$v(x) := \sum_{j=2}^{N} \tilde{v}(x_{j-1}) \psi_{-1,j}(x) + \sum_{j=1}^{N} \sum_{i=0}^{p_j-2} b_{ij} \psi_{i,j}(x)$$

and we set

$$\delta v := \tilde{v} - v = \sum_{j=2}^{N} \tilde{v}(x_{j-1}) \eta_{-1,j}(x) + \sum_{j=1}^{N} \sum_{i=0}^{p_j-2} b_{ij} \eta_{i,j}(x).$$

Then

$$B_T(u_{\tilde{v}}, \tilde{v}) = \sum_{j=1}^{N} \int_{I_j} u_{\tilde{v}} L^*_z v dx - \sum_{j=1}^{N-1} u_{\tilde{v}}(x_j) [\varepsilon \tilde{v}'(x_j)]$$

$$+ \sum_{j=1}^{N} \int_{I_j} u_{\tilde{v}} L^* \delta v dx.$$ 

We calculate

$$\int_{I_j} u_{\tilde{v}} L_z^* v dx = h_j \sum_{i=0}^{p_j-2} \frac{|b_{ij}|^2}{2i+1} = h_j S_j$$

and, by (3.15), (3.16),

$$- \sum_{j=1}^{N-1} u_{\tilde{v}}(x_j) [\varepsilon \tilde{v}'(x_j)] = \sum_{j=1}^{N-1} \rho_j^{-1} \left[ [\varepsilon \tilde{v}'(x_j)]^2 \right]$$

hence we find

$$B_T(u_{\tilde{v}}, \tilde{v}) \geq \sum_{j=1}^{N} h_j S_j + \sum_{j=1}^{N-1} \rho_j^{-1} \left[ [\varepsilon \tilde{v}'(x_j)]^2 \right] - \sum_{j=1}^{N} \| u_{\tilde{v}} \|_{L^2(I_j)} \| L_z^* \delta v \|_{L^2(I_j)}.$$  \hspace{1cm} (4.8)

Now

$$\| u_{\tilde{v}} \|_{L^2(I_j)}^2 = h_j \sum_{i=0}^{p_j-2} \frac{|b_{ij}|^2}{2i+1} + h_j \sum_{i=p_j-1}^{p_j} \frac{|a_{ij}|^2}{2i+1}.$$ 

Reasoning as in the proof of Theorem 3.1, we find then

$$\sum_{j=1}^{N} \| u_{\tilde{v}} \|_{L^2(I_j)}^2 \leq 4 \sum_{j=1}^{N-1} \left[ [\varepsilon \tilde{v}'(x_j)]^2 \right] + (p+3) \sum_{j=1}^{N} h_j S_j.$$  \hspace{1cm} (4.9)

Consider now $\| L_z^* \delta v \|_{L^2(I_j)}$. We have by (4.2), (4.3)

$$(L_z^* \delta v)_{ij} = \tilde{v}(x_{j-1}) \eta_{-1,j} + \tilde{v}(x_j) \eta_{-1,j+1} + \sum_{i=0}^{p_j-2} b_{ij} \eta_{i,j}.$$ 

Using (2.12), we estimate

$$\| L_z^* \delta v \|_{L^2(I_j)} \leq \| \tilde{v} \|_{L^\infty} \left( \| \eta_{-1,j} \|_{L^2(I_j)} + \| \eta_{-1,j+1} \|_{L^2(I_j)} \right) + \sum_{i=0}^{p_j-2} b_{ij} \| \eta_{i,j} \|_{L^2(I_j)}$$

$$\leq \| \tilde{v} \|_{L^\infty} \left( \| \eta_{-1,j} \|_{L^2(I_j)} + \| \eta_{-1,j+1} \|_{L^2(I_j)} \right)$$

$$+ (h_j S_j)^{1/2} \left( h_j^{-1} \sum_{i=0}^{p_j-2} (2i+1) \| \eta_{i,j} \|_{L^2(I_j)}^2 \right)^{1/2}.$$
\[ |L^*_{x_j} v|_{L^2(I_j)}^2 \leq 4 \|v\|_{L^\infty}^2 \Lambda_1 \Lambda_j + h_j S_j \Lambda_{2j} \quad j = 1, \ldots, N, \tag{4.10} \]

where we defined
\[ \Lambda_1 := \|\eta_{-1,j}\|_{L^2(\Omega_j)}^2 + \|\eta_{-1,j+1}\|_{L^2(\Omega_j)}^2 \]

and
\[ \Lambda_{2j} := h_j^{-1} \sum_{i=0}^{p_j-2} (2i + 1) \|\eta_{ij}\|_{L^2(\Omega_j)}^2. \]

Hence we may estimate with (4.9)
\[
\begin{aligned}
\sum_{j=1}^{N} \|u\|_{L^2(\Omega_j)} \|L^*_{x_j} v\|_{L^2(\Omega_j)} &
\leq \left( 4 \sum_{j=1}^{N-1} \frac{|\varepsilon \tilde{v}'(x_j)|^2}{\rho_j} + (p + 3) \sum_{j=1}^{N} h_j S_j \right)^{1/2} \left( 4 \Lambda_1 \|v\|_{L^\infty}^2 + \Lambda_2 \sum_{j=1}^{N} h_j S_j \right)^{1/2} \\
&\leq \max\{4, p + 3\}^{1/2} \left( \sum_{j=1}^{N} h_j S_j + \sum_{j=1}^{N-1} \frac{|\varepsilon \tilde{v}'(x_j)|^2}{\rho_j} \right)^{1/2} \left( 4 \Lambda_1 \|v\|_{L^\infty}^2 + \Lambda_2 \sum_{j=1}^{N} h_j S_j \right)^{1/2}
\end{aligned}
\tag{4.11}
\]

With (4.10), the embedding (2.12) and the definition of the $H^2_{\tau}$ norm we get further
\[
\|\tilde{v}\|_{H^2_{\tau}} \leq 2 \sum_{j=1}^{N} \|L^*_{x_j} v\|_{L^2(\Omega_j)}^2 + 2 \|L^*_{x_j} v\|_{L^2(\Omega_j)}^2 + \sum_{j=1}^{N-1} \frac{|\varepsilon \tilde{v}'(x_j)|^2}{\rho_j} \\
= 2(1 + \Lambda_2) \sum_{j=1}^{N} h_j S_j + 8C_1 \Lambda_1 \|\tilde{v}\|_{H^2_{\tau}}^2 + \sum_{j=1}^{N-1} \frac{|\varepsilon \tilde{v}'(x_j)|^2}{\rho_j}
\]

and, after regrouping terms, it follows that
\[
\sum_{j=1}^{N} h_j S_j + \sum_{j=1}^{N-1} \frac{|\varepsilon \tilde{v}'(x_j)|^2}{\rho_j} \geq D(\eta) \|\tilde{v}\|_{H^2_{\tau}}^2 \tag{4.12}
\]

provided $\Lambda_1, \Lambda_2$ are sufficiently small and
\[
D(\eta) := \frac{1 - 8C_1 \Lambda_1}{2(1 + \Lambda_2)}.
\]

The inequality which is converse to (4.12) also holds. To obtain it, we proceed as follows: we estimate
\[
\|\tilde{v}\|_{H^2_{\tau}}^2 = \sum_{j=1}^{N} \|L^*_{x_j} v + L^*_{x_j} \delta v\|_{L^2(\Omega_j)}^2 + \sum_{j=1}^{N-1} \frac{|\varepsilon \tilde{v}'(x_j)|^2}{\rho_j} \\
\geq \left( \frac{1}{2} - 5\Lambda_2 \right) \sum_{j=1}^{N} h_j S_j + \sum_{j=1}^{N-1} \frac{|\varepsilon \tilde{v}'(x_j)|^2}{\rho_j} - 20C_1 \Lambda_1 \|\tilde{v}\|_{H^2_{\tau}}^2
\]

and obtain after rearranging terms
\[
\sum_{j=1}^{N} h_j S_j + \sum_{j=1}^{N-1} \frac{|\varepsilon \tilde{v}'(x_j)|^2}{\rho_j} \leq C(\eta) \|\tilde{v}\|_{H^2_{\tau}}^2 \tag{4.13}
\]
where
\[ C(\eta) := \frac{1 + 20C_1\Lambda_1}{1/2 - 5\Lambda_2}. \]

From (4.13) and (4.9) we find
\[ \|u_\tilde{\psi}\|_{H^1_T}^2 \leq \gamma_M^2 \left\{ \sum_{j=1}^N h_j S_j + \sum_{j=1}^{N-1} \left[ \frac{\|\varepsilon\tilde{\psi}(x_j)\|}{\rho_j} \right] \right\} \leq \max\{5, p + 3\} C(\eta) \|\tilde{\psi}\|_{H^2_T}^2. \]  

(4.14)

Further, (4.8) and (4.11) imply with (4.12) and (4.13) the bound
\[ B_T(u_\tilde{\psi}, \tilde{\varphi}) \geq \frac{1}{\gamma_M} \left[ \frac{D(\eta)}{(C(\eta))^{1/2}} - \gamma_M^2 \left( 4C_1 \frac{D(\eta)}{C(\eta)} \Lambda_1 + D(\eta) \Lambda_2 \right) \right] \|u_\tilde{\psi}\|_{H^1_T} \|\tilde{\varphi}\|_{H^2_T} \]

from where the inf-sup condition (4.7) follows.

\[ \square \]

**Remark 4.2** The test functions \( \tilde{\psi}_{ij} \) in (4.2), (4.3) are **conforming**, i.e., globally in \( H^1_0(\Omega) \) and elementwise in \( H^2(I_j) \). As we shall show shortly, it is possible to obtain numerical approximations \( \tilde{\psi}_{ij} \) by solving the problems (3.8), (3.9) with a least squares FEM on a subgrid \( \mathcal{T} \) of \( T \). The assumption \( \tilde{\psi}_{ij} \in H^2(I_j) \) for \( I_j \in T \) then implies that the least squares FEM must be **locally** \( C^1 \) conforming. Although this can be achieved, we can also admit \( C^0 \)-approximations \( \tilde{\psi}_{ij} \) in Theorem 4.1, if we penalize the flux-jumps of \( \tilde{\psi}_{ij} \) on the subgrid appropriately. This will complicate the following analysis, but does not pose any essential difficulties.

The stability (4.7) together with the fact that the perturbed test functions are \( H^2_T \)-conforming and with Propositions A.4, A.3 and the approximation property Theorem 3.3 imply the following convergence result.

**Theorem 4.3** For any mesh \( T \) the hp FE-solution \( \tilde{u}_M \in S_0^p(\mathcal{T}) \) in (3.4) corresponding to the approximate test space \( S_0^p \) defined in (4.1) - (4.3) and satisfying (4.4), exists and is **quasi-optimal**, i.e., with \( C, \gamma_M \) of (4.7)
\[ \|u - \tilde{u}_M\|_{H^1_T} \leq (1 + \frac{\gamma_M}{C}) \|u - v\|_{H^1_T} \quad \forall v \in S_0^p. \]

(4.15)

In particular, if the coefficients \( a, b, \) and the right hand side \( f \) are analytic and satisfy (1.3), (1.5) - (1.7) and the mesh \( T = \mathcal{T}_{\kappa, \varepsilon} \) is chosen as in (3.24) with \( \kappa \) sufficiently small, we have robust exponential convergence, i.e.,
\[ \|u - \tilde{u}_M\|_{H^1_T} \leq C \exp(-\theta M) \]

(4.16)

where \( C, \theta > 0 \) are independent of \( \varepsilon, p \).

**Remark 4.4** The meshes \( \mathcal{T}_{\kappa, \varepsilon} \) considered in Theorem 3.3 are essentially the “minimal” meshes that can resolve the boundary layer behavior of the solution \( u \) in a \( p \)-version setting at a robust exponential rate. Clearly, the approximation results of the form (3.25)
hold true for any mesh $\mathcal{T}$ that contains one small element of size $O(\varepsilon p)$ at the outflow boundary, i.e., if $\mathcal{T}_{\varepsilon \varepsilon} \subset \mathcal{T}$. Due to the quasi-optimality (4.15), error estimates analogous to (4.16) hold for all meshes $\mathcal{T}$ with $\mathcal{T}_{\varepsilon \varepsilon} \subset \mathcal{T}$. These “minimal” meshes $\mathcal{T}_{\varepsilon \varepsilon}$ depend on the polynomial degree $p$. In practice, it may be more convenient to fix a mesh $\mathcal{T}$ and then increase $p$ until the desired accuracy is reached. For example, piecewise polynomials on a mesh which is graded geometrically towards the outflow boundary have approximation properties similar to the minimal meshes $\mathcal{T}_{\varepsilon \varepsilon}$ provided that the small element of the geometric mesh is $O(\varepsilon)$ (cf. [9]).

4.2 Computation of the Approximate Test Functions

To obtain approximate test functions $\tilde{\psi}_{ij}$, many strategies are possible: classical approaches use approximate analytical expressions (e.g., the Hemker test functions or the $\alpha$-quadratic upwinding mentioned above) or asymptotic expansions (e.g., in [19]). These semianalytical approaches work well for low order methods and one-dimensional problems; for two-dimensional problems, however, and to accommodate high $p$ together with arbitrary meshes, a fully numerical method for the computation of the test functions seems to be desirable.

Here we propose and analyze a local least squares FEM to approximate the $\psi_{ij}$ stably and completely computationally. The approach allows moreover for controlling the quantities $A_1, A_2$ in (4.5), (4.6) a-posteriori.

The plan for the remainder of this section is as follows. In Section 4.2.1 we will define the local least squares problems which define approximate test functions $\tilde{\psi}_{-1,j}, \tilde{\psi}_{ij}$ by minimizing appropriate quadratic functionals over finite dimensional spaces $A_j^{h_2}$. In this framework, the choice of the spaces $A_j^{h_2}$ determines completely the test functions $\tilde{\psi}_{-1,j}, \tilde{\psi}_{ij}$ and thus the method (3.4). The exact test functions are also solutions of singularly perturbed convection-diffusion equations with analytic coefficients. We will therefore choose $A_j^{h_2}$ as spaces of piecewise polynomials of degree $q$ on a two-element mesh (one small element at the outflow boundary of the local problem and one large element) in complete analogy to our approximation theory for the global solution $u_\varepsilon$. The details of these approximation results are provided in Sections 4.2.2, 4.2.3.

Other choices of the spaces $A_j^{h_2}$ lead to different methods. For example, for $p = 1$ and $A_j^{h_2}$ consisting of quadratic polynomials, the least squares method yields approximate test functions $\tilde{\psi}_{-1,j}$ very similar to those obtained by $\alpha$-quadratic upwinding. The Hemker test functions for $p = 1$ and constant coefficients $a, b$ may be obtained with our least squares method if one includes in the spaces $A_j^{h_2}$ exponentials which solve the homogeneous adjoint problem.

4.2.1 Approximate Test Functions via Local Least Squares FEM

To motivate the method, we define $A_j := (H^2 \cap H^1_0)(I_j), \; j = 1, ..., N$. We define further $\varphi_j(x)$ to be the piecewise linear “hat” function with $\varphi_j(x_{j-1}) = \varphi_j(x_{j+1}) = 0, \varphi_j(x_j) = 1, \varphi_j(x) = 0$ on $\Omega \setminus \bigcup_{j=1}^N I_j$.
Then \( \psi_{-1,j} - \varphi_{j-1} \in A_{j-1} \cup A_j \) and we have the variational characterization
\[
(\psi_{-1,j} - \varphi_{j-1})|_{I_k} = \arg\min_{\psi \in A_k} \| L^*_\varepsilon (\psi - \varphi_{j-1}) \|_{L^2(I_k)}^2, \quad k = j - 1, j,
\] (4.17)
for \( j = 2, \ldots, N \) and
\[
\psi_{ij}|_{I_j} = \arg\min_{\psi \in A_j} \| L^*_\varepsilon \psi - L_i \left( 2 \cdot \frac{m_j}{h_j} \right) \|_{L^2(I_j)}^2 \quad i = 0, \ldots, p_j - 2, j = 1, \ldots, N.
\] (4.18)

The assumptions (1.3), (1.4) imply that the operator \( L_\varepsilon \) and therefore also its adjoint \( L^*_\varepsilon \) are injective from \( A_j \rightarrow L^2(I_j) \). Hence the expression
\[
\| \psi \|_{A_j} := \| L^*_\varepsilon \psi \|_{L^2(I_j)}
\] (4.19)
is a norm on \( A_j \) (homogeneity and triangle inequality being obvious) and the quadratic functionals in (4.17), (4.18) are strictly convex and lower semicontinuous. Therefore (4.17), (4.18) admit unique solutions \( \psi_{-1,j}, \psi_{ij} \) which coincide with those in (3.8), (3.9).

For a numerical approximation of the functions \( \psi_{-1,j}, \psi_{ij} \), let \( A_{h}^{k} \subset A_j \) be a finite dimensional subspace. We obtain external approximate test functions \( \tilde{\psi}_{-1,j} \) by
\[
(\tilde{\psi}_{-1,j} - \varphi_{j-1})|_{I_k} = \arg\min_{\psi \in A_h^k} \| L^*_\varepsilon (\psi - \varphi_{j-1}) \|_{L^2(I_k)}^2, \quad k = j - 1, j
\] (4.20)
for \( j = 2, \ldots, N \) and internal approximate test functions \( \tilde{\psi}_{ij} \) by
\[
\tilde{\psi}_{ij}|_{I_j} = \arg\min_{\psi \in A_h^k} \| L^*_\varepsilon \psi - L_i \left( 2 \cdot \frac{m_j}{h_j} \right) \|_{L^2(I_j)}^2 \quad j = 1, \ldots, N.
\] (4.21)

These approximations are also uniquely defined. Moreover, they are optimal in the norm \( \| \cdot \|_{A_j} \), for we have
\[
\| \psi_{-1,j} - \tilde{\psi}_{-1,j} \|_{A_j} \leq \| \psi_{-1,j} - \varphi_{j-1} - \psi \|_{A_j} \quad \forall \psi \in A_h^k, \quad k = j - 1, j, \quad j = 2, \ldots, N,
\] (4.22)
\[
\| \psi_{ij} - \tilde{\psi}_{ij} \|_{A_j} \leq \| \psi_{ij} - \psi \|_{A_j} \quad \forall \psi \in A_h^k, \quad j = 1, \ldots, N.
\] (4.23)

Thus, the design of the approximation spaces \( A_{h}^{k} \) proceeds in the usual fashion: based on the regularity of the exact test functions \( \psi_{ij} \), we show that we can select the least squares approximation spaces \( A_{h}^{k} \) so that exponential convergence rates in the global norm \( \| \psi \|_A := \| L^*_\varepsilon \psi \|_{L^2(\Omega)} \) can be achieved.

**Remark 4.5** The calculation of the approximate test functions \( \tilde{\psi}_{-1,j}, \tilde{\psi}_{ij} \) can be done efficiently if one observes that eqs. (4.20), (4.21) represent completely decoupled local problems on the elements \( I_j \), which can be solved in parallel. Furthermore, on each element \( I_j \) the local least squares problems (4.20), (4.21) can be solved efficiently because the equivalent matrix formulations lead to problems with the same stiffness matrix and merely different right hand sides. Thus, once a convenient decomposition of the elemental least squares matrix is found (e.g., its \( LU \) decomposition), the approximate test functions \( \tilde{\psi}_{-1,j}|_{I_j}, \tilde{\psi}_{-1,j+1}|_{I_j}, \tilde{\psi}_{ij}, i = 0, \ldots, p_j - 2 \) can be obtained by \( p_j + 1 \) backsolves.
4.2.2 Approximation Results on the Reference Element

We begin our analysis with the following approximation result, quite analogous to Theorem 3.3. Introduce the $\varepsilon$ dependent norm $\| \cdot \|_{2,\varepsilon}$ on $H^2(I)$ by

$$\| u \|_{2,\varepsilon} := \varepsilon \| u'' \|_{L^2(I)} + \| u' \|_{L^2(I)} + \| u \|_{L^2(I)}$$  (4.24)

**Theorem 4.6** Let $u_\varepsilon$ be the solution of (1.1), (1.2). Assume that (1.3), (1.5)–(1.7) hold and let $\bar{p}$ and $T_{n,\varepsilon}$ be as in Theorem 3.3. Then there is $\kappa_0 > 0$ depending only on the constants of (1.3), (1.5)–(1.7) such that for every $0 < \kappa < \kappa_0$ there are $C, \sigma > 0$ independent of $p, \varepsilon$ and functions $v_p \in S_{\bar{p}}^2(T_{n,\varepsilon})$ such that

$$u_\varepsilon(\pm 1) = v_p(\pm 1), \quad \| u_\varepsilon - v_p \|_{2,\varepsilon} \leq C \varepsilon^{-1/2} e^{-\sigma p} \quad \forall p \in \mathbb{N}. \quad (4.25)$$

**Proof:** The proof is very similar to the proof of Theorem 3.3. We will therefore only highlight the main differences. For the asymptotic case $\kappa p \varepsilon \geq 1$, the claim follows easily as in the proof of Theorem 3.3. Let us consider the pre-asymptotic case $\kappa p \varepsilon < 1$. Choose $\mu, M$ as in (3.28) and use the decomposition (1.9) for $u_\varepsilon$. We get from Theorem 1.1 and Lemma 3.6

$$\left\| \left( w_M - i_p w_M \right)^{(l)} \right\|_{L^\infty(I)} \leq C e^{-\sigma p}, \quad l = 0, 1, 2.$$  

For the remainder $r_M$, we use Theorem 1.1 to get for $0 \leq n \leq 2$ and the implicit assumption on $p$ that $M \geq 1$:

$$\| r_M^{(n)} \|_{L^\infty(I)} \leq C \varepsilon^{1-n}(\varepsilon \mu k p M)^M \leq C \varepsilon^{1-n}(\varepsilon \mu k p)^n(\varepsilon \mu k p M)^{M-n+1} \leq C(\mu k p)^{n-1} q^{M-n+1}.$$  

Thus, an application of Lemma 3.5 yields

$$\left\| \left( r_M - i_p r_M \right)^{(l)} \right\|_{L^\infty(I)} \leq e^{-\sigma p}, \quad l = 0, 1, 2$$

for appropriately chosen $\sigma > 0$. Let us now turn to the approximation of the boundary layer function $u_\varepsilon^\pm$. The technical details are very similar to the proof of Theorem 5.1 of [15]. As in the proof of Theorem 3.3, let $l_1, l_2$ be the two linear maps from the reference element $I$ onto the two elements $I_1, I_2$. Consider first the approximation of the function $U(x) := (u_\varepsilon^+)'$ and let $\tilde{x} := 1 - \kappa p \varepsilon$ be the internal node of the mesh $T_{n,\varepsilon}$. Note that, up to a factor $\varepsilon^{-1}$, the function $U$ satisfies similar estimates as $u_\varepsilon^+$ by Theorem 1.1. Define the approximant $U_p \in S_{\bar{p}}^1(T_{n,\varepsilon})$ by

$$U_p(x) := \begin{cases} U(-1) + \frac{\varepsilon^{1/2} U(\tilde{x}) - U(-1)}{\tilde{x}+1}(x+1) & \text{on } I_1 \\ (i_p(U \circ l_2)) \circ l_2^{-1} - \frac{(1-\varepsilon)U(\tilde{x})}{\kappa p \varepsilon}(1-x) & \text{on } I_2. \end{cases}$$

We claim now that for $\kappa$ sufficiently small, there are $C, \sigma > 0$ such that

$$\left\| \left( U - U_p \right)^{(l)} \right\|_{L^2(I)} \leq C \varepsilon^{-1/2} e^{-\sigma p}, \quad l = 0, 1, \quad \forall p \in \mathbb{N}. \quad (4.26)$$
For the approximation on the small boundary layer element $I_2$, we calculate analogously to (3.30) (after absorbing the powers of $p$ arising from the use of Lemma 3.6 and choosing $\kappa_0$ sufficiently small)

$$\| (U \circ l_2 - (i_p(U \circ l_2)))^{(l)} \|_{L^\infty(I_2)} \leq C \varepsilon^{-l} e^{-\sigma_p}, \quad l = 0, 1.$$ 

Hence,

$$\| (U - (i_p(U \circ l_2) \circ l_2^{-1}))^{(l)} \|_{L^2(I_2)} \leq C \varepsilon^{-1} (\kappa p \varepsilon)^{1/2-l} e^{-\sigma_p}, \quad l = 0, 1.$$ 

We calculate further with $0 < \varepsilon \leq 1$:

$$\| \left(1 - \frac{\varepsilon^{1/2}}{\kappa p \varepsilon}(1-x)\right)^{l} \|_{L^2(I_2)} \leq |U(\bar{x})|(\kappa p \varepsilon)^{1/2-l}, \quad l = 0, 1.$$ 

Combining these two last estimates and observing that by Theorem 1.1 $|U(\bar{x})| \leq C \varepsilon^{-1} e^{-2\sigma_p/2}$, we get for some suitable $\sigma > 0$

$$\| (U - U_p)^{(l)} \|_{L^2(I_2)} \leq C \varepsilon^{-1/2-l} e^{-\sigma_p} \quad l = 0, 1.$$ 

Let us now consider the large element $I_1$. We have

$$\| (U - U_p)^{(l)} \|_{L^2(I_1)} \leq \| U^{(l)} \|_{L^2(I_1)} + \| U_p^{(l)} \|_{L^2(I_1)}.$$ 

By Theorem 1.1, $\| U^{(l)} \|_{L^2(I_1)} \leq C \varepsilon^{-1/2-l} e^{-2\sigma_p/2}$, and it is easy to verify that

$$\| U_p^{(l)} \|_{L^2(I_1)} \leq C \max (\varepsilon^{1/2} |U(\bar{x})|, |U(-1)|) \leq C \varepsilon^{-1/2} e^{-2\sigma_p/2}, \quad l = 0, 1.$$ 

Hence, we have proven (4.26). To conclude the proof of Theorem 4.6, we define the approximant $v_{p+1} \in S^{q+1,2} (\mathcal{T}, \varepsilon)$ by

$$v_{p+1}(x) := u_\varepsilon(-1) + \int_{-1}^{x} U_p(t) \, dt - \frac{1}{2} \left\{ \int_{-1}^{1} U_p(t) - U(t) \, dt \right\} (x + 1).$$ 

We note $v_{p+1}(\pm 1) = u_\varepsilon(\pm 1)$ and the observation

$$\left| \int_{-1}^{1} U_p(t) - U(t) \, dt \right| \leq C \varepsilon^{-1/2} e^{-\sigma_p}$$

$$(v_{p+1} - u_\varepsilon)(x) = \int_{-1}^{x} U_p(t) - U(t) \, dt - \frac{1}{2} \left\{ \int_{-1}^{1} U_p(t) - U(t) \, dt \right\} (x + 1)$$

allows us to conclude the argument.

□

This result immediately applies also to FE-approximations of the adjoint problem which will then enable us to analyze the approximation of the test functions.

**Corollary 4.7** Assume (1.4), (1.5)-(1.7). For $q \in \mathbb{N}$, $\kappa > 0$ set

$$\bar{q} = \{q, q\}, \quad \mathcal{T}^{*}_{\kappa, \varepsilon} = \{I_1, I_2\} \quad I_1 = [-1, -1 + \kappa \varepsilon], I_2 = [-1 + \kappa \varepsilon, 1] \quad \text{if} \ \kappa \varepsilon < 1,$$

$$\bar{q} = \{q\}, \quad \mathcal{T}^{*}_{\kappa, \varepsilon} = \{[-1, 1]\} \quad \text{if} \ \kappa \varepsilon \geq 1.$$ 

(4.27)
Let \( u^*_\varepsilon \) be the solution of the adjoint problem
\[
L^*_\varepsilon u^*_\varepsilon = f \quad \text{on } \Omega, \quad u^*_\varepsilon(\pm 1) = \alpha^\pm. \tag{4.28}
\]

Then there is \( \kappa_0 > 0 \) depending only on the constants in (1.4), (1.5)-(1.7) and \( \alpha^\pm \) such that the following holds. For each \( 0 < \kappa < \kappa_0 \) there are \( C, \sigma > 0 \) independent of \( q, \varepsilon \) and a sequence \( (v_\varepsilon) \) of functions in \( S^\gamma_2(T^{*\varepsilon}_\alpha) \) such that
\[
v^*_\varepsilon(\pm 1) = u^*_\varepsilon(\pm 1) \quad \text{and} \quad \|u^*_\varepsilon - v^*_\varepsilon\|_{L^2} \leq C\varepsilon^{-1/2}e^{-\sigma q} \quad \forall q \in \mathbb{N}
\]

**Proof:** The change of variables \( x \mapsto -x \) changes \( L^*_\varepsilon \) into a differential operator of the type of \( L_\varepsilon \) whose coefficients satisfy by (1.4) all the necessary conditions for Theorem 4.6 to imply the result.

We will use Corollary 4.7 to estimate the errors
\[
\|\tilde{\psi}_{ij} - \tilde{\psi}_{ij}\|_{s,j} = \|L^*_\varepsilon(\psi_{ij} - \tilde{\psi}_{ij})\|_{L^2(\Omega)}
\]
of the \( \tilde{\psi}_{ij} \) computed by the least squares methods (4.18), (4.21). Evidently, this will imply also bounds on \( \Lambda_1, \Lambda_2 \) in Theorem 4.1.

Clearly, Corollary 4.7 could be applied on \( \Omega_j \) after a scaling argument; however, rather than the general right hand side \( f \) in (4.28), we must also solve problem (4.3) with \( f = L_i, \ i = 0, \ldots, p_j - 2 \). To that end, let us formulate the following

**Proposition 4.8** Let \( T^{*\varepsilon}_\alpha \) be as in Corollary 4.7 and let \( u^*_\varepsilon \) be the solution of (4.28) where the right hand side \( f \) is a polynomial of degree \( p \). Then there is \( \kappa_0 > 0 \) depending only on the constants in (1.4), (1.5), (1.6) such that the following holds. For each \( 0 < \kappa < \kappa_0 \) there are constants \( C, \sigma, \tau > 0 \) and a sequence \( (v_\varepsilon) \) of functions in \( S^\gamma_2(T^{*\varepsilon}_\alpha) \) such that for all \( q \geq \tau p \)
\[
v^*_\varepsilon(\pm 1) = u^*_\varepsilon(\pm 1) \quad \text{and} \quad \|u^*_\varepsilon - v^*_\varepsilon\|_{L^2} \leq C\varepsilon^{-1/2}e^{-\sigma q}\left(|\alpha^-| + |\alpha^+| + \|f\|_{L^1}\right). \tag{4.29}
\]

For the proof of Proposition 4.8, we need the following lemma.

**Lemma 4.9 (Bernstein’s lemma)** Let \( I = [-1, 1] \). For every \( \rho > 1 \) there are \( C_\rho, \gamma_\rho > 0 \) such that for all polynomials \( P_\rho \) of degree \( p \)
\[
\|P_\rho^{(n)}\|_{L^\infty(I)} \leq C_\rho n! \gamma_\rho \rho^p \|P_\rho\|_{L^\infty(I)} \quad \forall n \in \mathbb{N}_0.
\]

**Proof:** For \( \rho > 1 \) denote \( \mathcal{E}_\rho \) the ellipse (in the complex plane) whose foci are \( \pm 1 \) and whose axes have lengths \( \rho + \rho^{-1}, \rho - \rho^{-1} \). By Bernstein’s Lemma (e.g., [8], III.15) the extension of \( P_\rho \) to the complex plane satisfies
\[
\|P_\rho\|_{L^\infty(\mathcal{E}_\rho)} \leq \rho^p \|P_\rho\|_{L^\infty(I)} \quad \forall \rho > 1.
\]
The claim of the lemma follows by Cauchy’s integral theorem for derivatives.

\[\square\]
Proof of Proposition 4.8: By linearity, we may write the solution $u^*_\varepsilon$ as the sum of $u_{\varepsilon,h} + u_{\varepsilon,p}$ where $u_{\varepsilon,h}$ solves (4.28) with homogeneous right hand side and inhomogeneous Dirichlet data $a^\pm$ and where $u_{\varepsilon,p}$ solves (4.28) with right hand side $f$ and homogeneous Dirichlet data. Corollary 4.7 implies (4.29) for $u_{\varepsilon,h}$. We may therefore concentrate on the approximation of $u_{\varepsilon,p}$. Fix $\rho > 1$. Lemma 4.9 implies

$$\|f^{(n)}\|_{L^\infty(I)} \leq \left(C \rho^p \|f\|_{L^\infty(I)}\right)^n \gamma^n \forall n \in \mathbb{N}_0.$$  \hfill (4.30)

Consider the scaled function

$$\tilde{u}_{\varepsilon,p} := \frac{u_{\varepsilon,p}}{\rho^p \|f\|_{L^\infty(I)}}$$

which solve the equation

$$L^*_\varepsilon \tilde{u}_{\varepsilon,p} = \tilde{f} \quad \text{on } I, \quad \tilde{u}_{\varepsilon,p}(\pm 1) = 0 \quad \text{on } I$$

$$\|f^{(n)}\|_{L^\infty(I)} \leq C \rho^p \gamma^n n! \quad \forall n \in \mathbb{N}_0$$

Hence, we may apply Corollary 4.7 to the function $\tilde{u}_{\varepsilon,p}$ and obtain the existence of functions $\tilde{v}_q \in S^{k,2}(T^*_\kappa X)$ with

$$\tilde{v}_q(\pm 1) = 0 \quad \|\tilde{u}_{\varepsilon,p} - \tilde{v}_q\|_{2,\varepsilon} \leq C \varepsilon^{-1/2} e^{-\sigma q} \quad \forall q \in \mathbb{N}$$

Scaling back, we obtain for the function $v_q := \rho^p \|f\|_{L^\infty(I)} \in S^{k,2}(T^*_\kappa X)$

$$v_q(\pm 1) = 0 \quad \|u_{\varepsilon,p} - v_q\|_{2,\varepsilon} \leq C \varepsilon^{-1/2} e^{-\sigma q} \rho^p \|f\|_{L^\infty(I)} \quad \forall q \in \mathbb{N}$$

As $q = q/2 + q/2 \geq q/2 + \tau p/2$ we see that choosing $\tau$ sufficiently large implies the statement of the proposition.

4.2.3 Analysis of the Local Least Squares FEM

In the preceding subsection, we analyzed the approximation properties of piecewise polynomials on the reference element $I$. In order to obtain bounds for the errors in (4.22), (4.23), let us introduce the linear transformations $l_k$ by

$$l_k : I \to I_k, \quad \hat{x} \mapsto l_k(\hat{x}) := m_k + \frac{h_k}{2} \hat{x}, \quad k = 1, \ldots, N.$$  \hfill (4.31)

Furthermore, for $k = 1, \ldots, N$ let us set

$$\hat{A}_{k} := A_k \circ l_k$$

$$\hat{u} := u \circ l_k \quad \forall u \in A_k$$

$$\varepsilon_k := \frac{2}{h_k} \varepsilon$$

$$\hat{L}^*_k := -\varepsilon_k \frac{\partial^2}{\partial \hat{x}^2} - a(l_k(\hat{x})) \frac{\partial}{\partial \hat{x}} + \frac{h_k}{2} [b(l_k(\hat{x})) - a'(l_k(\hat{x}))]$$
Note that $\hat{L}_{\varepsilon_k}^* \hat{u} = \frac{h_k}{2} (L_*^* u) \circ l_k$ for all $u \in A_k$. Note also that the coefficients of $\hat{L}_{\varepsilon_k}^*$ satisfy (1.4) (with the same $\gamma_1^*, \gamma_2^*$) and estimates similar to (1.5), (1.6). A straightforward calculation gives (recall (4.19))

$$\|v\|_{s,k} = \|L_*^* v\|_{L^2(I_k)} = \sqrt{\frac{2}{b_k}} \|\hat{L}_{\varepsilon_k}^* \hat{v}\|_{L^2(I)} \leq C h_k^{1/2} \|\hat{v}\|_{2,\varepsilon_k} \quad \forall v \in A_k$$

(433)

where the constant $C > 0$ depends only on the constants of (1.5), (1.6).

In order to get bounds on the expressions (4.22), (4.23), we note that for each $k = 1, \ldots, N$, the functions $\hat{\psi}_{-1,j} := \hat{\psi}_{-1,j} \circ l_k$, $\hat{\psi}_{i,k} := \hat{\psi}_{i,k} \circ l_k$ satisfy

$$\begin{align*}
\hat{L}_{\varepsilon_k}^* \hat{\psi}_{-1,j} &= 0 \quad \text{on } I, \quad \hat{\psi}_{-1,j}(-1) = 0, \hat{\psi}_{-1,j}(1) = 1 \quad \text{if } k = j - 1, \quad j = 2, \ldots, N, \\
\hat{L}_{\varepsilon_k}^* \hat{\psi}_{i,k} &= 0 \quad \text{on } I, \quad \hat{\psi}_{i,k}(0) = 0, \quad i = 0, \ldots, p_k - 2, \quad k = 1, \ldots, N.
\end{align*}$$

Here, the functions $L_j$ are the Legendre polynomials which satisfy $\|L_j\|_{L^2(0,1)} = 1$. With the notation of Proposition 4.8, let us choose finite dimensional subspaces $A_k^{h_q} \subset A_k$ as

$$\begin{align*}
A_k^{h_q} &:= S_0^{r,2}(T_{r,\varepsilon_k}^*) \circ l_k. \\
\end{align*}$$

(434)

Concerning the approximation of the functions $\hat{\psi}_{-1,j}$, $\hat{\psi}_{i,k}$, in the spaces $A_k^{h_q} = S_0^{r,2}(T_{r,\varepsilon_k}^*)$, Proposition 4.8 gives the existence of $C, \sigma > 0$ such that

$$\begin{align*}
\inf_{\hat{v}_q \in A_k^{h_q}} \left\| \hat{\psi}_{-1,j} - \hat{\varphi}_{j-1} - \hat{\psi}_q \right\|_{2,\varepsilon_k} &\leq C \varepsilon_k^{1/2} e^{-\sigma q} \quad \forall q \in \mathbb{N}, \\
\inf_{\hat{v}_q \in A_k^{h_q}} \left\| \hat{\psi}_{i,k} - \hat{\varphi}_{j-1} - \hat{\psi}_q \right\|_{2,\varepsilon_k} &\leq C \varepsilon_k^{1/2} h_k e^{-\sigma q} \quad \forall q \geq \tau p_k.
\end{align*}$$

(435)

Hence, with the choice (4.34) for the finite dimensional subspaces $A_k^{h_q} \subset A_k$ we obtain for (4.22), (4.23) with the aid of (4.33) and $\varepsilon_k = 2 \varepsilon / h_k$

$$\begin{align*}
\left\| \hat{\psi}_{-1,j} - \hat{\psi}_{-1,j}\right\|_{s,k} &\leq C \varepsilon^{-1/2} e^{-\sigma q} \quad \forall q \in \mathbb{N}, k = j - 1, \quad j = 2, \ldots, N, \\
\left\| \hat{\psi}_{i,k} - \hat{\psi}_{i,k}\right\|_{s,k} &\leq C h_k^{1/2} e^{-1/2 e^{-\sigma q}} \quad \forall q \geq \tau p_k, \quad k = 1, \ldots, N.
\end{align*}$$

(436)

These estimates allow us to control the expressions for $\Lambda_1$, $\Lambda_2$ arising in Theorem 4.1. We obtain

**Theorem 4.10** Let $T = \{I_1, \ldots, I_N\}$ be any mesh on $\Omega$ and $\vec{p}$ any degree vector. For $\kappa > 0$, define a subgrid mesh $T_{r,\varepsilon_k}^* := \bigcup_{k=1}^N T_{r,\varepsilon_k}^{*,k}$ where for each element $I_k$, the subdivision $T_{r,\varepsilon_k}^{*,k}$ is given by

$$\begin{align*}
T_{r,\varepsilon_k}^{*,k} &= \{l_k(J_1), l_k(J_2)\} \quad J_1 = [-1, -1 + \kappa q \varepsilon_k], \quad J_2 = [-1 + \kappa q \varepsilon_k, 1] \quad \text{if } \kappa q \varepsilon_k < 1, \\
T_{r,\varepsilon_k}^{*,k} &= \{I_k\} \quad \text{if } \kappa q \varepsilon_k \geq 1.
\end{align*}$$

Here $\varepsilon_k, h_k$ etc. are as in (4.32). Let furthermore the spaces $A_k^{h_q}$ be given by (4.34), or, equivalently, $A_k^{h_q} = S^{r,1}(T_{r,\varepsilon_k}^*) \cap A_k$ where $\vec{q} = (q_1, \ldots, q)$.
Then, for \( \kappa \) sufficiently small, there exist \( C, \sigma, \tau > 0 \) depending only on the constants of (1.4), (1.5), (1.6) such that the approximate test functions \( \tilde{\psi}_{-1,j}, \tilde{\psi}_{i,j} \) of (4.20), (4.21) satisfy (4.2), (4.3) and \( \Lambda_1, \Lambda_2 \) defined in (4.5), (4.6) can be estimated as follows.

\[
\begin{align*}
\Lambda_1 & \leq C N \varepsilon^{-1} e^{-\sigma q} \quad \forall q \in \mathbb{N}, \\
\Lambda_2 & \leq C \varepsilon^{-1} e^{-\sigma q} \quad \forall q \geq \tau p.
\end{align*}
\]

Proof: By (4.5), (4.35) we have

\[
\Lambda_1 \leq \sum_{j=2}^{N} \sum_{k=1}^{j} \|\psi_{-1,j} - \tilde{\psi}_{-1,j}\|_{a,k}^2 \leq C N \varepsilon^{-1} e^{-2\sigma q} \quad \forall q.
\]

For \( \Lambda_2, (4.6), (4.36) \) imply for all \( q \geq \tau p \)

\[
\Lambda_2 \leq \max_{1 \leq j \leq N} \left\{ h_j^{-1} \sum_{i=0}^{p_j-2} (2i+1) \|\psi_{i,j} - \tilde{\psi}_{i,j}\|_{s,j}^2 \right\} \leq C \max_{1 \leq j \leq N} \varepsilon^{-1} p_j^2 e^{-2\sigma q} \leq C \varepsilon^{-1} p^2 e^{-2\sigma q}.
\]

As we may assume \( \tau \geq 1 \), the factor \( p^2 \) can be absorbed in the exponential term at the expense of slightly reducing \( 2\sigma \) which concludes the proof of Theorem 4.10.

This result allows us finally to deduce the stability of the \( h_p \)-FEM with least squares approximations of the test functions.

**Corollary 4.11** Under the hypotheses of Theorem 4.10 there is \( \kappa_0 > 0 \) depending only on the constants in (1.3), (1.4), (1.5)–(1.7) such that for every \( 0 < \kappa < \kappa_0 \) there is \( \varepsilon > 0 \) such that for \( q \geq c \max(p, |\ln \varepsilon| + \ln N) \) the FEM (3.4) corresponding to \( S_L^p \) (computed by (4.20), (4.21)) is stable and hence quasi-optimal.

## 5 Numerical Example and Implementational Aspects

The aim of the present section is to illustrate the performance of the \( h_p \) FEM analyzed in this paper with particular attention to its robustness with respect to small viscosities \( \varepsilon \). We consider the model problem

\[
-\varepsilon u'' + u' = 1 \quad \text{on } \Omega = (-1, 1), \quad u_{\varepsilon}(\pm 1) = 0. \tag{5.1}
\]

The exact solution has a boundary layer at the outflow boundary and is given by

\[
u_{\varepsilon} = x + 1 + \frac{2}{1 - e^{-2/\varepsilon}} \left( e^{-2/\varepsilon} - e^{-(1-x)/\varepsilon} \right).
\]

Guided by the approximation result Theorem 3.3, we choose for the trial space the spaces \( S_{0,1}^p(\mathcal{T}_{h,\varepsilon}) \) with \( \kappa = 1 \) (cf. (3.1)) where the meshes \( \mathcal{T}_{h,\varepsilon} \) are given by (3.24). A specific basis of \( S_{0,1}^p \) is given by the usual piecewise linear “nodal” shape functions and the integrated Legendre polynomials (the “internal” shape functions). For this particular problem, the basis functions \( \psi_{-1,j}, \psi_{i,j} \) of the spaces of \( L \)-splines (cf. (3.8), (3.9)) can be determined in
the form of antiderivatives of exponentials times Legendre polynomials of degree up to $p$. Note that, since the coefficients of (5.1) are constant, the classical Hemker test functions arise for $p = 1$. Hence, for $p > 1$, in this example our scheme could be viewed as an $hp$ version of the “Hemker test function” method.

Our numerical experiments were performed using MATLAB, i.e., with double precision (16 decimal) accuracy. They had the following aims: i) to show that robust exponential convergence is indeed achievable by $hp$-FEM, ii) to demonstrate that the method remains numerically stable as $\varepsilon$ decreases to the order of machine precision (note that unlike e.g., the SDFEM, our method does not introduce any artificial viscosity into the computation) and iii) to assess the impact of inaccurate test functions and numerical quadrature on the stability and the robustness of the scheme.

Let us first address a few implementational aspects. If the test functions are approximated using piecewise polynomials (as proposed in Section 4), then the load vector is created in the usual way requiring some numerical integration, in general. Further, the local adjoint problems determining the (approximate) test functions may be solved completely independently and in parallel.

The stiffness matrix corresponding to $B_T(u, v)$ consists of two parts: a mass matrix like term stemming from the domain integrals and a finite-volume like term stemming from the flux-jumps at interelement boundaries. For the mass matrix part, the test functions $\psi_{-1,j}$, $\psi_{i,j}$ need not be known completely. Rather, only $L_1^* \psi_{-1,j}$, $L_1^* \psi_{i,j}$ (which are chosen to be Legendre polynomials and hence known) are required. For the flux jumps, the only information employed from the Dirichlet problems (3.8), (3.9) are the normal derivatives in the endpoints, i.e., a Dirichlet-to-Neumann map is needed. In Section 4, we proposed a least squares method to approximate the test functions, but for the generation of the stiffness matrix, any sufficiently accurate Dirichlet-to-Neumann map may be taken.

For the present, constant coefficient model problem (5.1), exact representations of the test functions as antiderivatives of Legendre polynomials times a boundary layer function are available which must be integrated numerically. The next lemma shows how functions of boundary layer type can be integrated numerically in a very efficient way using standard Gaussian quadrature formulas. In our calculations, the numerical evaluation of integrals over elements of boundary layer functions against polynomials were performed based on the ideas of this “two-element” quadrature scheme with $q$ points in each subelement.

**Lemma 5.1** Let $w$, $f$ be analytic on $\Omega = (-1, 1)$ and satisfy

$$
\|f^{(n)}\|_{L^\infty(\Omega)} \leq C_f(K_f)^n n!, \quad |w^{(n)}(x)| \leq C_w(K_w)^n \varepsilon^{(1-x)/\varepsilon} \max(n, \varepsilon^{-1})^n, \quad x \in \Omega, \quad \forall n \in \mathbb{N}_0, \varepsilon \in (0, 1].
$$

For $q \in \mathbb{N}$ let $T_{\kappa, \varepsilon}$ be the “two-element” meshes introduced in (3.24) (with $q$ taking the role of $p$) and denote by $G_q(T_{\kappa, \varepsilon}, w f)$ the composite Gaussian quadrature rule with $q$ points in each element applied to the function $w f$. Then there is $\kappa_0 > 0$ such that for $0 < \kappa < \kappa_0$ there are $C, \sigma > 0$ (independent of $\varepsilon, q$) such that

$$
\left| \int_{\Omega} w(x)f(x) \, dx - G_q(T_{\kappa, \varepsilon}, w f) \right| \leq C\varepsilon^{-\sigma}, \quad q = 1, 2, 3, ...
$$

(5.2)

If $f$ is a polynomial of degree $p$ with $\|f\|_{L^\infty(\Omega)} \leq 1$ then under the assumption $q \geq p + 1$ estimate (5.2) holds with $C, \sigma$ independent of $\varepsilon, p, q$. 

Proof: Observe that for the composite Gaussian quadrature formula of order \( q \) the quadrature error may be estimated by twice the size of the integration domain times a \( L^\infty \) best approximation of the integrand:

\[
\left| \int_\Omega w(x) f(x) \, dx - G_q(\mathcal{T}_{\kappa_\varepsilon}, w f) \right| \leq 2 |\Omega| \inf_{\pi_{2q-1}} \| w f - \pi_{2q-1} \|_{L^\infty(\Omega)}
\]

where the infimum is taken over all piecewise polynomials \( \pi_{2q-1} \) of degree \( 2q - 1 \) on the mesh \( \mathcal{T}_{\kappa_\varepsilon} \). Let \( \pi_{q-1}(f), \pi_q(w) \) be the piecewise Gauss-Lobatto interpolants of \( f, w \) of orders \( q - 1, q \), respectively. Upon setting \( \pi_{2q-1} := \pi_{q-1}(f) \pi_q(w) \) and using the stability result (3.26), we can bound

\[
\| w f - \pi_{2q-1} \|_{L^\infty(\Omega)} \leq \| f - \pi_{q-1}(f) \|_{L^\infty(\Omega)} \| w \|_{L^\infty(\Omega)} + C_{GL}(1 + \ln q) \| f \|_{L^\infty(\Omega)} \| w - \pi_q(w) \|_{L^\infty(\Omega)}. \tag{5.3}
\]

The proof of Theorem 3.3 shows that for the function \( w \), which is of boundary layer type,

\[
\| w - \pi_q(w) \|_{L^\infty(\Omega)} \leq Ce^{-\sigma q_0}
\]

with \( C, \sigma > 0 \) independent of \( q, \varepsilon \) provided that \( \kappa \) is sufficiently small. A similar estimate holds for \( \| f - \pi_{q-1}(f) \|_{L^\infty(\Omega)} \) by Lemma 3.6, and thus the right hand side of (5.3) is exponentially small (in \( q \)). Finally, if \( f \) is a polynomial of degree \( p \) and \( q \geq p + 1 \), then the term involving \( f - \pi_{q-1}(f) \) vanishes in (5.3), and hence the claim of the lemma follows.

\[ \square \]

Remark 5.2 Note that Lemma 5.1 shows that accurate numerical integration of boundary layer functions is possible without constructing special, “exponentially” weighted quadrature rules. The present approach works even without explicit knowledge of the boundary layer function.

As we pointed out in Remark 3.4, the value of \( \kappa_0 \) is in principle available from the proof. For the special weight function \( w = e^{-(1-\varepsilon)/\kappa} \), the analysis of [15] shows that \( \kappa_0 \geq 4/\varepsilon \). Furthermore, note that the use of geometrically refined meshes outlined in Remark 4.4 eliminates the need for bounds on \( \kappa_0 \). We chose \( \pi_{2q-1} \) as the product of (piecewise) polynomials of degree \( q - 1 \) and \( q \). However, other “splittings” are possible and thus the condition \( q \geq p + 1 \) for polynomial right hand sides \( f \) may be relaxed to a condition of the form \( q \geq \tau p \) with \( \tau > 1/2 \).

In Figs. 1–4, we present the results of calculations with very large values of \( q \) corresponding to practically exact evaluation of the stiffness matrix and load vector. In Figs. 1, 2 we show the \( L^2 \) convergence versus the polynomial degree (note: \( \dim S_{0}(T_{1,\varepsilon}) = 2p - 1 \) typically). As predicted by Theorem 4.3 we have robust exponential convergence: for small values of \( \varepsilon \) the error curves are practically on top of each other. For our two-element meshes, Theorem 4.3 also gives exponential convergence of the point value at the one internal node (at \( 1 - \varepsilon p \)). Inspection of the error at that point shows superconvergence: nodal exactness (up to machine precision) is obtained for all values of \( p \) and \( \varepsilon \). To demonstrate the robustness of the method in the \( L^\infty \) norm is the objective of the experiments reported in Figs 3, 4. Here, the discrete \( L^\infty \) error is defined by the maximum error in sampling points.
which are chosen as follows. $\Omega$ is subdivided into three sampling windows $(-1, 1 - 11p\varepsilon)$, $(1 - 11p\varepsilon, 1 - p\varepsilon)$, $(1 - p\varepsilon, 1)$ and in each window $10^4$ sampling points are uniformly distributed. The graphs indicate that also in the maximum norm, the finite element solution features indeed the robust exponential convergence predicted in Theorem 3.3.

Next, we address the effect of approximate test functions on the performance of the method. By reducing the order of integration $q$ we introduce into the stiffness matrix and the load vectors errors which correspond to the effect of approximate test functions (which, being piecewise polynomials, would be integrated exactly). Figs. 5-8 show the effect of inexact integration. The numerical integrations of exponentials times Legendre polynomials were now performed with composite Gaussian rules of order $q = 1$, $q = p/4 + 1$, $q = p/2 + 1$, $q = 3/4p + 1$, and $q = p + 1$. In Figs. 5, 6, we show the error for “exactly integrated” load vectors, but low integration order in the flux jumps of the stiffness matrix for $\varepsilon = 10^{-5}$, $\varepsilon = 10^{-10}$. We observe that even with severe underintegration, $q = 1$, practically no instability occurs, but a consistency error of size $O(\sqrt{\varepsilon})$ is introduced. A similar phenomenon is observed for the quadrature errors of the right hand side, shown in Figs. 7, 8, where now the stiffness matrix has been integrated “exactly”. Here, underintegration (e.g., $q = 1$) leads to a saturation at an error level of roughly $O(\varepsilon)$. Despite these consistency errors the stability is not compromised, even by severe underintegration with $q = 1$, which might explain the success of $h$-version schemes based on often very crude, analytical approximations of the upwinded test functions. It appears, however, that, in order to avoid the $O(\sqrt{\varepsilon})$ and $O(\varepsilon)$ saturation errors observed in Figs. 5-8, one has indeed to increase the quadrature order (resp. the polynomial degree $q$ of the approximate test functions) in accordance with Corollary 4.11, i.e., proportional to $\max(p, |\ln \varepsilon| + \ln N)$.

Let us finally comment on the sparsity pattern and the solution of the resulting linear system. If the basis of the $L$-splines is chosen as in (3.8), (3.9), and if the basis of the trial space is the usual “nodal” and “internal” shape functions, then the resulting stiffness matrix is a banded matrix with bandwidth $O(p)$ (cf. Fig. 9 for the case of a four-element mesh and $p = 10$, i.e., 39 unknowns).

In summary, our numerical experiments show that our error estimates are sharp and that they describe accurately the performance of the Petrov-Galerkin $hp$-FEM: the impact of the quadrature order on the stability and consistency follows closely the predictions made in Corollary 4.11 and the method performs uniformly well for the viscosity parameter $\varepsilon$ ranging from $\varepsilon = 1$ to the order of machine precision, $\varepsilon = 10^{-16}$. In the latter case, within the machine precision the hyperbolic limiting problem is calculated. Thus, the method presented here also opens new avenues to generate $p$ and $hp$ version FEM for hyperbolic problems via a numerical vanishing viscosity approach.

A Appendix: Analysis of Petrov-Galerkin FEM

Here we present some abstract results that are used repeatedly in our analysis. We merely cite those that are classical (see [1]), and derive some extensions required by us.

Throughout this appendix, $X$ and $Y$ denote reflexive Banach spaces equipped with norms $\|\cdot\|_X$ and $\|\cdot\|_Y$, respectively, and $B : X \times Y \to \mathbb{R}$ denotes a bilinear form which is
continuous, i.e.
\[ |B(u, v)| \leq C_1 \|u\|_X \|v\|_Y. \tag{A.1} \]

By \( Y' \) we denote the dual space to \( Y \). It is also a Banach space equipped with the norm
\[ \|F\|_{Y'} = \sup_{0 \neq v \in Y} \frac{|F(v)|}{\|u\|_Y}. \tag{A.2} \]

**Proposition A.1** Assume that \( B(\cdot, \cdot) \) satisfies
\[ \inf_{0 \neq u \in X} \sup_{0 \neq v \in Y} \frac{B(u, v)}{\|u\|_X \|v\|_Y} \geq \gamma > 0 \tag{A.3} \]
and
\[ \forall 0 \neq v \in Y : \sup_{u \in X} B(u, v) > 0. \tag{A.4} \]

Then, for every \( F \in Y' \), the abstract saddle point problem:
\[ u \in X : \quad B(u, v) = F(v) \quad \forall v \in Y \tag{A.5} \]
admits a unique solution \( u \) satisfying the a-priori estimate
\[ \|u\|_X \leq \frac{C_1}{\gamma} \|F\|_{Y'}. \tag{A.6} \]

For a proof, we refer to [1].

An equivalent form of the stability condition (A.3), (A.4) is

**Proposition A.2** If \( B(\cdot, \cdot) \) satisfies
\[ \inf_{0 \neq v \in Y} \sup_{0 \neq u \in X} \frac{B(u, v)}{\|u\|_X \|v\|_Y} \geq \tilde{\gamma} > 0 \tag{A.7} \]
and
\[ \forall 0 \neq u \in X : \sup_{v \in Y} B(u, v) > 0 \tag{A.8} \]
then also (A.3) and (A.4) hold with \( \gamma = \tilde{\gamma}/C_1 \).

**Proof:** Let \( G \in X' \) satisfy \( \|G\|_{X'} = 1 \) and consider the auxiliary problem:
\[ \tilde{v}_G \in Y : \quad B(w, \tilde{v}_G) = G(w) \quad \forall u \in X. \tag{A.9} \]

Clearly, the bilinear form \( C(\cdot, \cdot) \) defined via \( C(v, u) := B(u, v) \) satisfies by our assumptions (A.7),(A.8) all requirements for Proposition A.1 with \( X \) and \( Y \) interchanged, however. Hence \( \tilde{v}_G \) exists, is unique and satisfies
\[ \|\tilde{v}_G\|_Y \leq \frac{C_1}{\tilde{\gamma}} \|G\|_{X'} = \frac{C_1}{\tilde{\gamma}}. \tag{A.10} \]
We prove that $B(\cdot, \cdot)$ satisfies (A.3): given $0 \neq u \in X$, select $G(\cdot) \in X'$ such that $G(u) = 1$ and define $v_u := \|u\|_X \tilde{v}_G$. Then, by (A.9),

$$B(u, v_u) = \|u\|_X B(u, \tilde{v}_G) = \|u\|_X^2,$$

and, by (A.10),

$$\|v_u\|_Y \leq \frac{C_1}{\gamma} \|u\|_X.$$

This implies (A.3) with $\gamma = \hat{\gamma} / C_1$. (A.4) follows directly from (A.7).

Let now $X_M \subset X$, $Y_M \subset Y$ be closed subspaces. We consider the abstract FE-discretization of (A.5)

$$u_M \in X_M : \quad B(u_M, v) = F(v) \quad \forall v \in Y_M.$$  \hspace{1cm} (A.11)

The following result, due to Babuška [1], addresses the convergence of (A.11) in terms of the approximability of $u$ from $X_M$ and in terms of the stability implied by the test function space $Y_M$.

**Proposition A.3** Assume

$$\inf_{0 \neq u \in X_M} \sup_{0 \neq v \in Y_M} \frac{B(u, v)}{\|u\|_X \|v\|_Y} \geq \gamma_M > 0$$  \hspace{1cm} (A.12)

and

$$\forall 0 \neq v \in Y_M : \quad \sup_{u \in X_M} B(u, v) > 0.$$  \hspace{1cm} (A.13)

Then, for every $F \in Y'$, (A.11) admits a unique solution $u_M$ which satisfies the error estimate

$$\|u - u_M\|_X \leq (1 + \frac{C_1}{\gamma_M}) \inf_{w \in X_M} \|u - w\|_X.$$  \hspace{1cm} (A.14)

Frequently in this paper, one does not have the inf-sup conditions (A.12), (A.13), but rather the adjoint set of conditions

$$\inf_{0 \neq v \in Y_M} \sup_{0 \neq u \in X_M} \frac{B(u, v)}{\|u\|_X \|v\|_Y} \geq \hat{\gamma}_M > 0,$$  \hspace{1cm} (A.15)

and

$$\forall 0 \neq u \in X_M : \quad \sup_{v \in Y_M} B(u, v) > 0.$$  \hspace{1cm} (A.16)

An application of Proposition A.2 to the finite dimensional case gives

**Proposition A.4** Assume (A.1), (A.15), (A.16). Then the inf-sup conditions (A.12), (A.13) hold with

$$\gamma_M = \hat{\gamma}_M / C_1.$$
Appendix: Regularity

The goal of this subsection is to prove Theorem 1.1, i.e., obtain bounds on the $u_\varepsilon$ and its derivatives which depend only on the constants $C_\alpha, C_\beta, C_f, \gamma_\alpha, \gamma_\beta$, and $\gamma_1, \gamma_2$ of Section 1.2.

We introduce two more expressions $\lambda^-, \lambda^+$ which can be controlled in terms of $\gamma_1, \gamma_2$:

$$\lambda^- := \max \left\{ \frac{a - \sqrt{a^2 + 4b\varepsilon}}{2\varepsilon}, 0 \right\} \leq \gamma_2,$$

$$\lambda^+ := \min \left\{ \frac{a + \sqrt{a^2 + 4b\varepsilon}}{2\varepsilon}, \frac{a}{\varepsilon} \right\} \geq \frac{a}{2\varepsilon}.$$

Let us first get bounds on the solution $u_\varepsilon$ by the maximum principle.

**Lemma B.1** There is $C > 0$ depending only on the constants appearing in (1.5), (1.6), (1.3), and $C_f$ such that the solution $u_\varepsilon$ of (1.1) satisfies

$$\|u_\varepsilon\|_{L^\infty} \leq C, \quad \|u'_\varepsilon\|_{L^\infty} \leq C\varepsilon^{-1}.$$

**Proof:** The lemma is proved by the maximum principle (cf. [13], Chap. 1, Sec. 5, Thm. 11; note that the function $w := e^{-\lambda^+(1-x)}$ satisfies the assumptions of Thm. 11). Consider the functions

$$\psi_\pm := |\alpha^-|e^{\lambda^-(1+x)} + |\alpha^+|e^{-\lambda^-(1-x)} + \frac{x + 1}{\gamma_1}\|f\|_{L^\infty} e^{\lambda^-(1+x)} \mp u_\varepsilon.$$

Then $\psi_\pm(\pm 1) \geq 0$, $L_\varepsilon \psi_\pm \geq 0$ and thus by the maximum principle

$$|u_\varepsilon(x)| \leq |\alpha^-|e^{\lambda^-(1+x)} + |\alpha^+|e^{-\lambda^-(1-x)} + \frac{x + 1}{\gamma_1}\|f\|_{L^\infty} e^{\lambda^-(1+x)} \|f\|_{L^\infty}.$$

The bound on $\|u_\varepsilon\|_{L^\infty}$ follows. Let us introduce the shorthand

$$A(x) := \frac{1}{\varepsilon} \int_x^1 a(t) dt.$$

For the derivative estimate, we estimate $u'_\varepsilon(1)$ first. Multiplying the differential equation by $e^{A(x)}$, then integrating from $x$ to 1 and then multiplying again by $e^{-A(x)}$ gives

$$u'_\varepsilon(x) = e^{-A(x)} u'_\varepsilon(1) - \frac{1}{\varepsilon} \int_x^1 b(t) e^{A(t)-A(x)} u_\varepsilon(t) dt + \frac{1}{\varepsilon} \int_x^1 f(t) e^{A(t)-A(x)} dt$$

Integrating this equation from $-1$ to 1 yields

$$\alpha^+ - \alpha^- = u'_\varepsilon(1) \int_{-1}^1 e^{-A(x)} dx - \frac{1}{\varepsilon} \int_{-1}^1 e^{-A(x)} \int_x^1 b(t) e^{A(t)} u_\varepsilon(t) dt dx + \frac{1}{\varepsilon} \int_{-1}^1 e^{-A(x)} \int_x^1 f(t) e^{A(t)} dt dx$$

Some simple algebra shows that we have

$$\int_{-1}^1 e^{-A(x)} dx \leq \frac{\varepsilon}{a} \quad \text{(B.2)}$$

$$\int_{-1}^1 e^{-A(x)} dx \geq \frac{\varepsilon}{\|a\|_{L^\infty}}(1 - e^{2\varepsilon/a}) \quad \text{(B.3)}$$

$$\frac{1}{\varepsilon} \int_x^1 \int_{-1}^1 e^{A(t)-A(x)} dt dx \leq \frac{2}{\varepsilon} e^{-\lambda^+(1-x)} \quad \text{(B.4)}$$

$$\frac{1}{\varepsilon} \int_x^1 e^{A(t)-A(x)} e^{-\lambda^+(1-t)} dt \leq \frac{2}{\varepsilon} e^{-\lambda^+(1-x)} \quad \text{(B.5)}$$
Therefore,
\[
|u_\varepsilon'(1)| \leq \left( |\alpha^+ - \alpha^-| + \left( \|b\|_{L^\infty} \|u_\varepsilon\|_{L^\infty} + \|f\|_{L^\infty} \right) \frac{2\gamma}{a} \right) \frac{\|a\|_{L^\infty}}{\varepsilon} (1 - e^{-2\pi/\varepsilon})^{-1}.
\]
Thus, inserting this estimate in (B.1) yields
\[
|u_\varepsilon'(x)| \leq |u_\varepsilon'(1)| + \frac{2}{\varepsilon} \|b\|_{L^\infty} \|u_\varepsilon\|_{L^\infty} + \frac{2}{\varepsilon} \|f\|_{L^\infty}
\]
and thus the claim of the lemma.

\[\square\]

**Lemma B.2** Let \( u_\varepsilon^+ \) be the outflow boundary layer defined in (1.9). Then there is \( C > 0 \) depending only on the constants of (1.3), (1.5)–(1.7) such that
\[
|u_\varepsilon^+(x)| \leq e^{-2(1-x)/2\varepsilon}, \quad |u_\varepsilon^{+'}(x)| \leq C\varepsilon^{-1} e^{-2(1-x)/(2\varepsilon)}.
\]

**Proof:** In fact, a stronger statement holds true:
\[
|u_\varepsilon^+(x)| \leq e^{-\lambda^+(1-x)}, \quad |u_\varepsilon^{+'}(x)| \leq C\varepsilon^{-1} e^{-\lambda^+(1-x)}.
\]
The pointwise estimate follows immediately from the comparison functions used in the proof of Lemma B.1. The derivative estimate follows similarly to the one in Lemma B.1. We obtain the same bound on \( u_\varepsilon'(1) \) and then insert this bound in (B.1) making use of (B.5). The observation \( \lambda^+ \geq a/(2\varepsilon) \) concludes the proof of the lemma.

\[\square\]

**Lemma B.3** Let \( u_\varepsilon^+ \) be the outflow boundary layer defined in (1.9). Then there are constants \( C_1, C_2 > 0 \) depending only on the constants of (1.3), (1.5), (1.6) such that
\[
C_1\varepsilon^{-1} \leq u_\varepsilon^+(1) \leq C_2\varepsilon^{-1}.
\]

**Proof:** Lemma B.2 gives the upper bound. For the lower bound, we analyze the proof of Lemma B.2 more carefully. Let the function \( A \) be defined as in the proof of Lemma B.2. The equation following (B.1) reads
\[
1 = u_\varepsilon^{+'}(1) \int_{-1}^1 e^{-A(x)} \, dx - \frac{1}{\varepsilon} \int_{-1}^1 e^{-A(x)} \int_{-1}^1 b(t) e^{A(t)} u_\varepsilon^+(t) \, dt \, dx
\]
By the maximum principle and Lemma B.2 we have
\[
0 \leq u_\varepsilon^+(x) \leq e^{-\lambda^+(1-x)}, \quad x \in \overline{\Omega}
\]
Thus, if \( b \geq \bar{b} \geq 0 \) on \( \overline{\Omega} \), then the claim of the Lemma follows with (B.3). Let therefore \( \bar{b} < 0 \). We obtain again with \( u_\varepsilon^+ \geq 0 \)
\[
u_\varepsilon^{+'}(1) \int_{-1}^1 e^{-A(x)} \, dx \geq 1 - \frac{1}{\varepsilon} \int_{-1}^1 e^{-A(x)} \int_{-1}^1 |\bar{b}| e^{A(t)} u_\varepsilon^+(t) \, dt \, dx
\]
(8.5)
Using \( a \leq a(x) \), \(-A(x) = a(x)/\varepsilon\), and (B.7) we obtain
\[
\frac{1}{\varepsilon} \int_{-1}^{1} e^{-A(x)} \int_{x}^{1} |h| e^{A(t)} u_{\varepsilon}(t) \ dt \ dx \leq \int_{-1}^{1} \frac{a(x)}{\varepsilon} e^{-A(x)} \int_{x}^{1} |h| e^{A(t)} u_{\varepsilon}(t) \ dt \ dx \\
\leq \frac{1}{\varepsilon} \left[ e^{-A(x)} \int_{x}^{1} |h| e^{A(t)} u_{\varepsilon}(t) \ dt \right]_{-1}^{1} + \frac{1}{\varepsilon} \int_{-1}^{1} |h| u_{\varepsilon}(t) \ dt \\
\leq \frac{1}{\varepsilon} \int_{-1}^{1} |h| e^{-A(x)} \ dt \leq \frac{2|h|}{a^2} \leq \frac{2|h|}{a^2}.
\]

Inserting this estimate in (B.8) and noting that \(|h| = -\delta\) leads to
\[
u_{\varepsilon}^{-1} \int_{-1}^{1} e^{-A(x)} \ dx \geq 1 - \frac{2|\delta|}{a^2} = \left( \frac{a^2}{\varepsilon} \right)^2 \geq \gamma_{H}^2 a^2
\]
and thus the claim of the lemma by estimate (B.3).

\[ \square \]

\textit{Proof of (1.12), (1.13):} Let us first prove (1.12). Choose \( K > \max \{ 1, \gamma_f, \gamma_a, \gamma_b \} \) such that
\[
\left[ \frac{C_f}{K^2} + \frac{C_a}{K} \frac{1}{1 - \gamma_a/K} + \frac{C_b}{K^2} \frac{1}{1 - \gamma_b/K} \right] \leq 1.
\]

By Lemma B.1, we may now choose the constant \( C \geq 1 \) such that (1.12) holds true for \( n = 0, 1 \). Let us now proceed by induction on \( n \). We assume that the induction hypothesis (1.12) holds for \( 0 \leq \nu \leq n+1 \) and show that it holds for \( n+2 \). Differentiating the differential equation (1.1) \( n \) times (note that we know already that \( u_\varepsilon \) is analytic) we get
\[
-\varepsilon u_{\varepsilon}^{(n+2)} = f^{(n)} - (a u_{\varepsilon}^{(n)}) - (b u_{\varepsilon}^{(n)}) = f^{(n)} - \sum_{\nu=0}^{n} \binom{n}{\nu} \left[ a^{(\nu)} u_{\varepsilon}^{(n+1-\nu)} + b^{(\nu)} u_{\varepsilon}^{(n-\nu)} \right].
\]

Using the induction hypothesis, we get
\[
\varepsilon \| u_{\varepsilon}^{(n+2)} \|_{L^\infty(\Omega)} \leq \| f^{(n)} \|_{L^\infty(\Omega)} + C \sum_{\nu=0}^{n} \binom{n}{\nu} \left[ C_a \gamma_a^{\nu} \max (n + 1 - \nu, \varepsilon^{-1})^{n+1-\nu} + C_b \gamma_b^{\nu} \max (n - \nu, \varepsilon^{-1})^{n-\nu} \right].
\]

Exploiting the estimates
\[
\binom{n}{\nu} \max (n + 1 - \nu, \varepsilon^{-1})^{n+1-\nu} \leq n^\nu \max (n + 1, \varepsilon^{-1})^{n+1} \leq \max (n + 1, \varepsilon^{-1})^{n+1}
\]
\[
\binom{n}{\nu} \max (n - \nu, \varepsilon^{-1})^{n-\nu} \leq n^\nu \max (n, \varepsilon^{-1})^{n-\nu} \leq \max (n + 1, \varepsilon^{-1})^{n+1}
\]
\[
\| f^{(n)} \|_{L^\infty(\Omega)} \leq C_f \gamma_f^{n} \nu! \leq C_f \max (n + 1, \varepsilon^{-1})^{n+1}
\]

we obtain
\[
\varepsilon \| u_{\varepsilon}^{(n+2)} \|_{L^\infty(\Omega)} \leq \| f^{(n)} \|_{L^\infty(\Omega)} + C K^{n+2} \max (n + 1, \varepsilon^{-1})^{n+1} \sum_{\nu=0}^{n} \frac{C_a}{K} \left( \frac{\gamma_a}{K} \right)^{\nu} + \frac{C_b}{K^2} \left( \frac{\gamma_b}{K} \right)^{\nu}
\]
\[
\leq C K^{n+2} \max (n + 1, \varepsilon^{-1})^{n+1} \left[ \frac{C_f}{K^2} + \frac{C_a}{K} \frac{1}{1 - \gamma_a/K} + \frac{C_b}{K^2} \frac{1}{1 - \gamma_b/K} \right].
\]
By the choice of $K$ the expression in the brackets is bounded by 1 which concludes the induction argument after dividing both sides by $\varepsilon$.

The proof of (1.13) proceeds in the same fashion; the only difference is that Lemma B.2 instead of Lemma B.1 is used to start the induction argument.

Now we turn to the proof of (1.14)–(1.16). Recall the definition of the terms $u_j$ of the asymptotic part $w_M$ in the decomposition (1.9). In order to control these terms, we need the following lemma.

**Lemma B.4** Let $G$ be an open, complex neighborhood of $I = [-1, 1]$. Assume that the functions $\Lambda, a, u_0 : G \to \mathbb{C}$ are holomorphic and bounded on $G$. Assume additionally that $|a| \geq a > 0$ on $G$. Then there are constants $C, K_1, K_2 > 0$ depending only on $a$, $\|a'\|_{L^\infty(G)}$, $\|\Lambda\|_{L^\infty(G)}$, $\|\Lambda'\|_{L^\infty(G)}$, and $G$ such that the functions $u_j$ defined recursively as in (1.8) satisfy

$$\|u_j^{(n)}\|_{L^\infty(I)} \leq C K_1^j K_2^n j! \|u_0\|_{L^\infty(G)} \quad \forall j, n \in \mathbb{N}_0.$$  

**Proof:** Again, we will prove a stronger statement. Without loss of generality we may assume that $G$ is star shaped with respect to $z = -1$. For $\delta > 0$ (sufficiently small) denote $G_\delta := \{z \in G \mid \text{dist}(z, \partial G) > \delta\}$. Then we claim that there are $C, K > 0$ such that

$$\|u_j\|_{L^\infty(G_\delta)} \leq C K^j \delta^{-j} j! \|u_0\|_{L^\infty(G)} \quad \forall j \in \mathbb{N}_0.$$  

The proof of the lemma follows from this estimate by Cauchy’s integral theorem for derivatives.

It remains therefore to establish the claim. We proceed by induction on $j$. It is true for $j = 0$ and for any $C \geq 1$. We write

$$u_{j+1}(z) = e^{-\Lambda(z)} \int_{-1}^{z} e^{\Lambda(t)} \frac{1}{a(t)} u_j''(t) \, dt = e^{-\Lambda(z)} \left[ e^{\Lambda(t)} \frac{1}{a(t)} u_j'(t) \right]_{-1}^{z} + e^{-\Lambda(z)} \int_{-1}^{z} e^{\Lambda(t)} \Lambda'(t) a(t) + a'(t) \frac{1}{a(t)^2} u_j'(t) \, dt.$$  

Hence there is $C_1 > 0$ such that

$$\|u_{j+1}\|_{L^\infty(G_\delta)} \leq C_1 \|u_j'\|_{L^\infty(G_\delta)}.$$  

By Cauchy’s integral theorem, we have for $0 < \kappa < 1$ using the induction hypothesis:

$$\|u_{j+1}\|_{L^\infty(G_\delta)} \leq C_1 \frac{2 \pi K \delta}{(K \delta)^2} \|u_j\|_{L^\infty(G_{(1-\kappa)\delta})} \leq C_1 C j! K^j (1 - \kappa)^{-j} \frac{1}{K \delta} \|u_0\|_{L^\infty(G)} \leq C (j + 1)! K^{j+1} \delta^{-(j+1)} \|u_0\|_{L^\infty(G)} \frac{C_1}{K(j + 1)(1 - \kappa)^2 \kappa}.$$
Choosing $\kappa = 1/(j + 1)$, we observe that there is $c_1 > 0$ such that $c_1 \leq (j + 1)\kappa(1 - \kappa)^j$ for all $j \geq 1$. Hence, choosing $K > 0$ such that $C_1/(Kc_1) \leq 1$ finishes the induction argument.

This lemma puts us in position to conclude the proof of Theorem 1.1.

Proof of (1.14)–(1.16): Let us begin with (1.14). We see immediately that the assumptions of Lemma B.4 are satisfied: The size of the complex neighborhood $G$ and the constants $C$, $K_1$, $K_2$ can be controlled by the constants of (1.3), (1.5)–(1.7). Also $\|u_0\|_{L^\infty(G)}$ can be controlled in terms of these constants. Hence, the terms $u_j$ satisfy

$$
\|u_j^{(n)}\|_{L^\infty(\Omega)} \leq C j! n! K_1^n K_2^n \quad \forall j \in \mathbb{N}_0, n \in \mathbb{N}_0.
$$

Thus

$$
\|w_M^{[n]}\|_{L^\infty(\Omega)} \leq C K_2^n n! \sum_{j=0}^M \varepsilon^j K_1^n j! \leq C K_2^n n! \sum_{j=0}^M (\varepsilon K M)^j.
$$

This last sum can be bounded by a constant under the condition $\varepsilon K M \leq 1$ if we choose $K > K_1$.

An immediate consequence of (1.14) is (1.16): $C_M = \alpha^+ - w_M(1)$ and $w_M(1)$ can be controlled by (1.14) under the assumption $\varepsilon M K \leq 1$. Finally, the remainder $r_M$ satisfies (1.11). An application of Lemma B.1 (note that we only need to control the $L^\infty$ norm of the right hand side for Lemma B.1 to hold) together with (1.14) gives the claim of (1.16) for $n = 0, 1$ and the differential equation satisfied by $r_M$ gives the claim for $n = 2$.
