## Abstract

Novel approaches to service bundling in the passenger transportation market are enabled by technology driven innovations and give rise to so called “Mobility as a Service” (MaaS) concepts. These approaches promise to increase service quality of existing public transportation, decrease car ownership, reduce private vehicle miles and lower the environmental burden of the transportation system. However, the potential effects of service bundles in the passenger transportation market are still largely unclear.

In a competitive market, the potential success of transportation service bundles follows consumer valuation of the bundles as compared to valuation of stand-alone services. Thus, the difference between the bundle and sum-of-parts willingness to pay (WTP) is an indicator of service integration valuation, which effects the competitiveness of the service bundles. In this study, several discrete choice experiments were conducted to indirectly estimate consumers’ WTP and service integration valuation.

The results indicate that public transportation, car-sharing, and park and ride services are valued significantly higher when offered in a bundle instead of as a stand-alone service. Bicycle-sharing, electrical bicycle (e-bike) sharing and taxi services are valued lower. Potential consumers also exhibit a high WTP for a smartphone application that integrates the services and manages ticketing and payment.

Consequently, pure bundles for all transportation modes may not be

optimal strategy for mobility providers. Instead, it may be better to bundle public transportation with car-sharing and park and ride to exploit the higher WTP and offer (electric) bicycle-sharing and taxi services on a pay-as-you-go basis. In this way, profitability of a public transportation system could be increased.

## 1. Introduction

Mobility as a service (MaaS) describes the bundling of services in the passenger transportation market into a single coherent service. Mobility services are offered on a digital platform that acts as a gateway, providing a journey planner or mobility assistant with a single mode of payment and a single ticket. Service bundling enabled by internet and communication technology (ICT) systems better matches supply to demand and may render multimodal trips more efficient. Transportation service bundling is thus expected to decrease transaction costs between mobility providers and consumers. A mobility assistant that analyzes long-term travel behavior could add additional value by personalizing the service. The assistant could provide individuals with suggestions to optimize the journey, while taking personal goals into account (e.g. cost reduction or a recommended distance by foot or bicycle per week). In bundles with public transportation at the core, efficiency gains could lead to an increased market share for public transportation and a decrease in private vehicle ownership. The associated environmental benefits (through fewer *private* vehicle-miles travelled) are also in the best interest of the public; reducing the environmental burden of the transportation system is highly relevant (i.e. reducing emissions of greenhouse gases, carbon monoxide, nitric oxide, fine particles and volatile organic compounds). Bundling, however, requires a high level of organization and coordination among several mobility providers (which may be in competition with one other). Efficiency gains and the added value of transportation service bundling must clearly outweigh coordination costs. If coordination costs are higher than the efficiency gains and the added value, it would not be profitable to offer transportation service bundles.

Bundling has been the focus of a rich economic literature, especially in the subfields of production economics and marketing. Examples for bundling are the combination of airline tickets with a meal on board or software bundles such as Microsoft Office. Bundling of products and services can result in numerous advantages for firms. Bundling can serve as a measure to implement corporate strategies (e.g. to introduce new products or to deter competitors from entering a market). Under certain conditions, bundling can also be an effective tool for price discrimination when knowledge about consumer preferences is limited (McAfee et al., 1989; Sheikhzadeh and Elahi, 2013; Vamosiu, 2018). For transportation service bundling and MaaS, the goal is not a vertical integration by a monopoly provider, but an integration

1 of mobility services across different mobility providers. Whether consumers  
2 value a bundle higher than the sum of its parts depends on whether the  
3 integration is viewed as performance enhancing. For transportation service  
4 bundling, the difference in valuation between bundles and sum-of-parts is of  
5 key importance to profitability and the competitive positioning compared to  
6 traditional services. In a competitive market, the bundling of transportation  
7 services thus directly follows consumer valuation of the bundling and the  
8 value added by the mobility platform. Knowledge about the added value of  
9 integration must therefore be determined and discussed.

10 In order to investigate how consumers value transportation services and  
11 service bundles, an online survey was conducted in the canton of Zurich in  
12 May 2018. The introductory part of the survey gathered information about  
13 study participants' demand for mobility, current consumption of mobility  
14 services, ownership and usage of mobility tools, personal mobility budget,  
15 socio-demographic information and attitudes toward public transportation,  
16 cycling and car-ownership. Several discrete choice experiments (DCE) were  
17 embedded in the survey: for each transportation service, a DCE was con-  
18 ducted to estimate indirectly the willingness to pay (WTP). The WTP for  
19 service bundles containing the same services were also determined in a sepa-  
20 rate DCE in order to be able to calculate the WTP differences and thus the  
21 consumers' valuation of integration. The experiment allows for the following  
22 questions to be answered: Is there a perceived utility of the ICT platform; i.e.  
23 the smartphone application? Do consumers view bundling of transportation  
24 services as utility enhancing? Are consumers more likely to consume new  
25 mobility services (such as park and ride or bicycle-sharing) when offered in  
26 a bundle? The analysis also reveals which mobility services are perceived  
27 as complements or substitutes and thus determines which services should be  
28 offered together.

## 29 **2. Background**

### 30 *2.1. Literature Review*

31 Existing literature in transportation research is grouped into three main  
32 streams: case studies of trials of ICT-enabled transportation service bundling  
33 (i.e. UbiGo in Gothenburg), DCEs investigating consumer demand for hy-  
34 pothetical bundles and literature reviews of potential consequences from  
35 bundling. Surprisingly, transportation studies have completely neglected  
36 bundling literature in the fields of production economics and marketing.

1 (Only Heikkilä (2014) has looked beyond the confines of transportation.)  
2 This also explains why the terminology used in product bundling has not  
3 been used in the transportation literature. Product and service bundling  
4 is common practice in several industries, including airlines, telecommunica-  
5 tions and information technology (IT). ICT solutions are naturally used for  
6 the integration of bundled services when conducive to the integration process.  
7 Bundling in the passenger transportation market is comparable to bundling  
8 in other sectors and consequently, the general bundling literature is used to  
9 fill in the information gaps.

10 Sochor et al. (2014) investigated the case of UbiGo, one of the first oper-  
11 ational trials of an integrated mobility service. The factors motivating and  
12 hindering adoption were assessed using a mixed methods approach that in-  
13 cluded surveys, interviews, focus groups and workshops. The results showed  
14 that users' motivation for participating in the operational trial in the first  
15 place was merely curiosity. Curiosity was replaced by convenience, flexibility  
16 and economic considerations as the study progressed. This is expected, as cu-  
17 riosity naturally fades, and as the study unfolded, the convenience and price  
18 could be better assessed. Incentive systems, where awarded points could be  
19 used for sponsor services, only played a minor role and could not compensate  
20 for economic disadvantages. Factors hindering user adoption were the price  
21 (more expensive than current mobility choices), the accessibility of alterna-  
22 tive transportation options, and not enough demand for mobility services  
23 (Sochor et al., 2014). However, this study must be taken with a grain of salt,  
24 as the survey techniques are untraceable from the report, and no statistical  
25 modelling was conducted. There was no control group (non-participants were  
26 not surveyed during and after the trial) and a counterfactual was missing.  
27 Thus, it is unclear whether external factors contributed to the change in the  
28 stated motives.

29 Matyas and Kamargianni (2017) conducted a stated preference (SP) ex-  
30 periment to investigate the choice process of purchasing transportation ser-  
31 vice bundles. Study participants were presented with three "fixed" bundles  
32 (which in marketing terms would be called "pure bundles") and a "menu op-  
33 tion" (a mixed bundle). The bundles included public transportation, bicycle-  
34 sharing, taxi and car-sharing. Additional features were also included; e.g.  
35 access to a minivan in the car-sharing option, or a 10 minute pickup guaran-  
36 tee for the taxi service. The survey process included an introductory survey,  
37 GPS tracking and a survey after tracking for the SP experiment. In the  
38 experiment, each respondent was presented with four choice tasks. In total,

1 80 participants completed the whole survey including the SP experiment.  
2 The results were analyzed using a multinomial logit model (MNL) that in-  
3 cluded 236 choice observations. Public transportation was found to be the  
4 core element of transportation service bundles. However, the study exhibits a  
5 number of limitations. More advanced modelling was recommended for later  
6 work. Indeed, an MNL was not the correct choice given the panel structure  
7 of the data. As each respondent completed four choice tasks, the data most  
8 likely exhibited correlations of unobserved factors of the decision makers and  
9 the MNL would not be suitable in this case. Furthermore, there was no  
10 investigation of the WTP for the elements of the bundles. Additionally, it  
11 is unclear if the GPS tracking of the subject was necessary for investigat-  
12 ing transportation service bundling. GPS tracking requires significant effort  
13 (i.e. recruitment, data cleaning etc.) and therefore the sample size is often  
14 limited. Reproducibility of a study also suffers in these cases because the  
15 tools are often not openly available and not standardized. A travel diary or  
16 survey is sufficient to collect information about current mobility behavior in  
17 most cases. The questions raised by Matyas and Kamargianni (2017) were  
18 interesting and important given the potential effects of transportation ser-  
19 vice bundling on the wider transportation system. It would be worthwhile to  
20 conduct similar studies in several countries in order to gain robust insights  
21 into the potential of service bundling in the transportation market.

22 Kamargianni et al. (2016) assessed several integrated mobility schemes  
23 around the world with regard to the level of integration along three dimen-  
24 sions: ticket and payment, prepayment option (“mobility package”) and ICT  
25 integration. Several operational systems with a high integration level were  
26 identified: Hannovermobil, EMME in Montpellier, and three systems in the  
27 Netherlands that are directed at business travelers (Mixx, NS-Business, Ra-  
28 diuz Total Mobility). SHIFT in Las Vegas, UbiGo in Gothenburg, and the  
29 Helsinki model were listed as highly integrated systems that offer a prepay-  
30 ment option. An integration measure and ranking system were also con-  
31 structed within this study. The categories of “ticket integration”, “payment  
32 integration”, “ICT integration”, and “mobility package integration” were  
33 equally weighted for the integration measure. However, equal weights for the  
34 categories may not have been justified. For example, ICT and ticket integra-  
35 tion should be much more important than payment integration, as payment  
36 for the individual services could also be handled via credit card. It is also  
37 unclear as to whether “Mobility package integration” (the ability to prepay  
38 a certain amount) is a necessary element of MaaS.

1 Hensher (2017) discussed the implications of ICT-enabled transportation  
2 service bundling on future bus services. The author argued that there are  
3 contexts where bundling may not be appropriate (such as school bus services).  
4 Thus, it is more likely that several transportation services will coexist in the  
5 future, and bundling will complement the landscape of services. Although  
6 some claims of the effects of MaaS were overexaggerated, it is possible that  
7 with further ICT solution availability, the broker role in passenger trans-  
8 portation market could become more important. It is too early to speculate  
9 on the possible effects of bundling on modal shares or car ownership. Vehicle  
10 sharing as a part of transportation service bundles, however, may lead to  
11 more efficient utilization of existing infrastructure. This however, highly de-  
12 pends on the services that are part of the bundle. The question of scalability  
13 was also raised, and must be addressed prior to potential effects due to mode  
14 shifts and car ownership.

15 An important stream of literature on bundling that is also relevant for the  
16 passenger transportation market can be found in the fields of marketing and  
17 production economics. Previous research in these fields provides accurate and  
18 concise terminology for different types of product and service bundles. Inves-  
19 tigated topics have included the role of complementarity and substitutability  
20 of the bundled services (McAfee et al., 1989; Yan et al., 2014) as well as  
21 optimal bundling strategies in different competitive situations; i.e. perfect  
22 and imperfect competition (Adams and Yellen, 1976; Vamosiu, 2018). The  
23 incentive to bundle when consumers' valuation are non-additive (Armstrong,  
24 2013), the implications of bundling on marketing (Stremersch and Tellis,  
25 2002) and bundling as an instrument to deter competitors from entering a  
26 market (Eppen et al., 1991) have also been investigated. Other studies have  
27 looked into bundling for specific industries (Hui et al., 2012; Sobolewski and  
28 Kopczewski, 2017). Sobolewski and Kopczewski (2017) investigated comple-  
29 mentarity and substitutability of service components in telecommunication  
30 bundles. The WTP of stand-alone services versus bundled services were also  
31 investigated through a direct survey. This approach is problematic though,  
32 as the resulting WTP estimates could be highly biased (Breidert et al., 2006).

33 A clear definition of bundling terms and strategies was provided by Stremersch  
34 and Tellis (2002, p. 57). Bundling was defined as "...the sale of two  
35 or more separate products in one package". The two main dimensions of  
36 bundling are price bundling and product bundling. Price bundling is "the  
37 sale of two or more separate products as a package at a discount, without any  
38 integration of the products". Product bundling refers to the integration of

1 the products at any price. Another important classification is between “pure  
2 bundles” and “mixed bundles.” Pure bundling refers to a situation where a  
3 firm only sells bundles and the bundled products are not offered separately.  
4 In a mixed bundle the products can also be purchased separately. These  
5 two dimensions of bundling could also be used in transportation research to  
6 classify bundles in the passenger transportation market. The legality and  
7 optimality of bundling strategies, the effect of competition on the bundling  
8 decision, and consumers’ perception of bundles were discussed. These issues  
9 have not yet been investigated for the case of transportation service bundles  
10 and are thus still unclear.

11 The theoretical foundation of behavioral bundling research and investiga-  
12 tions into the likelihood of purchase are particularly relevant for a consumer  
13 valuation study. Stremersch and Tellis (2002) showed that behavioral re-  
14 search on bundling is rooted in prospect theory (Kahneman and Tversky,  
15 1979) and mental accounting (Thaler, 1985). Price sensitivity decreases and  
16 purchase likelihood increases when consumers are presented with a single  
17 bundle price instead of a list of prices (Drumwright, 1992; Gaeth et al., 1990;  
18 Yadav, 1994). Thus, the “menu plan” (mixed bundle) investigated by Matyas  
19 and Kamargianni (2017) for transportation services would not be an optimal  
20 strategy for firms. Consumers perceive a list of prices as multiple losses,  
21 which negatively affects purchase likelihood. This also implies that price  
22 sensitivity for a bundle should be lower than for the sum of the prices of the  
23 stand-alone services. Furthermore, Eppen et al. (1991) showed that product  
24 and service bundling can be used as a strategy to introduce new products.  
25 In the transportation market, this could be used for the introduction of new  
26 transportation options, such as bicycle-sharing or car-sharing.

## 27 *2.2. MaaS as a Concept and the Definition of MaaS*

28 The concept of MaaS has been used to describe a special case of service  
29 bundling in the passenger transportation market. It was introduced in a  
30 Master’s thesis for the city of Helsinki by Heikkilä (2014) and investigated  
31 the potential of ICT to make the transportation system more efficient. MaaS  
32 was originally defined as “a system, in which a comprehensive range of mo-  
33 bility services are provided to customers by mobility operators” (Heikkilä,  
34 2014). This system would therefore be a service itself. MaaS, as a term, has  
35 since been widely accepted by most transportation researchers. However, a  
36 clear definition of when a service can be regarded as “MaaS” is still lack-  
37 ing. Kamargianni et al. (2016) stated that MaaS “... is one of the novel

1 mobility concepts that could assist in achieving seamless mobility” and that  
2 MaaS “stands for buying mobility services instead of buying the means of  
3 transportation”. The idea of replacing individually owned vehicles with the  
4 consumption of mobility services was introduced. Kamargianni et al. (2016)  
5 also stated that MaaS is based on three main elements: ticket and payment  
6 integration, the mobility package and ICT integration. It is clear that ticket  
7 and payment integration is necessary to provide customer-friendly service  
8 bundling and that the use of modern ICT applications with location-based  
9 services (LBS) are key to the concept. It is unclear, however, how the “mobil-  
10 ity package” (described as the ability to prepay services) is a main element.  
11 Prepayment is not a necessary condition, as customers could also be charged  
12 by credit card or by monthly bill. The UbiGo users found prepayment to be  
13 a limitation of the service (Sochor et al., 2014). Hensher (2017) defined MaaS  
14 as a service that “combines transportation services from public and private  
15 transportation providers through a unified gateway that creates and manages  
16 the trip, which users can pay for with a single account”. This definition is  
17 concise and stresses bundling, while avoiding unnecessary elements such as  
18 prepayment. The definition also excludes single services without bundling  
19 (e.g. Uber) and avoids ambiguity and its consequences (e.g. a shift away  
20 from privately owned vehicles).

21 While the definition above is general and concise enough to describe a  
22 large number of systems, the term “MaaS” is still misleading, because public  
23 transportation, taxis, car-sharing, bicycle-sharing etc. are already services  
24 in an economic sense (i.e. they are intangible, cannot be stored, and are  
25 produced and consumed at the same time). “Mobility as a Service” would  
26 indicate “the ability to move as a service”, which is exactly what existing  
27 public transportation services offer. Calling the concept “transportation as  
28 a service” does not resolve the issue. A term that describes the bundling of  
29 transportation services with an ICT system at its core should therefore stress  
30 the bundling aspect or the fact that bundling is achieved through ICT, not  
31 the service<sup>1</sup>. Thus, the term “transportation service bundling” will be used.

---

<sup>1</sup>The term “MaaS” seems to be inspired by the term “Software as a Service” or “SaaS”. SaaS describes the provision of software on a subscription basis that is hosted centrally instead of on customers’ computers. The functions are accessed over a thin client, e.g. a web browser. In the case of SaaS, the term is appropriate because it describes a shift from delivery as a software product to a centrally provided service that allows accessing the software’s functions. Bundling of different software products is not necessarily part

1 If the ICT aspect of the system must be stressed, then the concept will be  
2 referred to as “ICT-enabled transportation service bundling”.

3 The ICT system that provides the gateway to the bundled transporta-  
4 tion services increases accessibility of those services by providing information  
5 about spatiotemporal availability that is tailored to the customer’s location.  
6 On a software-level, such services are commonly referred to as location-based  
7 services (LBS), which are clearly at the core of ICT-enabled transportation  
8 service bundling. The ICT system should also be able to identify possible  
9 transportation options or a combination thereof, as well as additional de-  
10 tails such as trip time and cost to the user. In the future, the market may  
11 also increasingly adopt Internet of Things (IoT) solutions that may render  
12 the interaction between transportation services and the user more efficient  
13 and comfortable (e.g. such that the user interaction time is minimized).  
14 Examples of this include more efficient automated check-in for public trans-  
15 portation vehicles (e.g. for pricing purposes) that does not solely rely on  
16 GPS data provided by the user, or the consideration of battery charge of on  
17 shared electric vehicles or e-bikes by the mobility platform.

### 18 **3. Methods**

#### 19 *3.1. Survey Instrument*

20 In order to investigate ICT-enabled transportation service bundling, an  
21 online survey was conducted in the canton of Zurich, Switzerland<sup>2</sup>. The  
22 survey consisted of an introductory part, six DCEs for transportation services  
23 in the canton as stand-alone, and one DCE for a mobility service bundle that  
24 included the same services as the first six DCEs. The last part of the survey  
25 was a 12-item measure for technological commitment (Neyer et al., 2016)  
26 and a nine-item scale to capture environmental attitudes (Diekmann et al.,  
27 2009). All participants were asked to complete the whole survey. The first

---

of SaaS. MaaS is not appropriate an analogy because for example in the case of public transportation, there is no shift from a product to a service and bundling is the main idea. Adding to the confusion is the different usage of the term “service” in IT and economics. In IT, “service” refers to a software functionality, while in economics it describes an immaterial exchange of value.

<sup>2</sup>The canton of Zurich has a population of approximately 1.5 million people. With a population density of approximately 860 persons/ $km^2$ , the canton is mostly urbanized, but it also includes rural parts.

1 part of the survey contained questions on sociodemographics, participants'  
2 current consumption of mobility services, kilometers driven by private car  
3 and current mobility expenditures. The survey instrument was designed  
4 such that the average response time did not exceed 30 minutes.

5 The survey was geographically constrained to the canton of Zurich, Switzer-  
6 land, in order to ensure that all participants faced the same options for mo-  
7 bility. (Each canton usually has its own local public transport providers with  
8 different pricing schemes.) Participants were recruited by a private company,  
9 Intervista<sup>3</sup>, which maintains a panel of registered persons who have consented  
10 to participating in surveys. The survey was completed by 1000 participants  
11 with a response rate of 23.6%. Quotas were set on age, education, gender  
12 and public transportation season ticket ownership such that the sample was  
13 comparable to the population of the canton of Zurich in the Swiss household  
14 travel survey “Mikrozensus Mobilität und Verkehr” (MZMV) (Swiss Federal  
15 Statistical Office (BFS), 2017).

16 Table 1 shows a comparison of a selected set of variables of this sur-  
17 vey with the MZMV. When considering the sociodemographic attributes of  
18 gender, age and income, the two samples are very similar. Driver’s license  
19 holders were slightly overrepresented in this survey (by 5.1%), as well as  
20 holders of the GA travel card from the national train company (SBB) that  
21 allows unrestricted travel access on all public transportation networks (by  
22 5.9%). Holders of the half-fare ticket were underrepresented (by 10.3%).

---

<sup>3</sup>Company website: <https://survey.intervista.ch/>, last accessed: July 2018.

Table 1: Comparison of survey sample with the Swiss household travel survey (MZMV 2015)

Variable	Value	Survey	MZMV 2015 (Canton Zürich)
Gender	Female	50.9%	48.1%
	Male	49.1%	51.9%
Age	18-35	25.6%	20.7%
	36-50	29.2%	29.4%
	51-65	25.2%	27.4%
	66+	20.1%	22.5%
Income/mo	Below CHF 4000	17.5%	18.0%
	CHF 4'001 - 8'000	39.9%	40.1%
	CHF 8'001 bis 12'000	23.8%	24.8%
	More than CHF 12000	18.8%	16.2%
Driver's license	Yes	85.9%	80.8%
	No	14.1%	19.2%
PT season ticket	Half-fare card	48.3%	38.0%
	GA travel card	15.7%	9.8%
	None	31.1%	29.4%

### 1 3.2. DCE Design

2 Table 2 shows the attributes and attribute levels of the DCEs for the  
3 stand-alone transportation services, and table 3 shows the service bundles.  
4 All choice tasks included an opt-out option (i.e. a way to decline the offer)  
5 and the designs were constrained in order to exclude unreasonable prices.  
6 (The values in a DCE are a design choice and should be as realistic as possible.  
7 It would for example not make sense to offer the choice of a public  
8 transportation season ticket for the whole country for CHF 20 when it is  
9 priced at CHF 340 in the real market.) For all experiments, D-optimal  
10 designs were constructed with the software “NGENE” (Rose et al., 2014).  
11 Each experiment for the stand-alone services included two attributes: the  
12 cost and a description of the extent (minutes travelled, kilometers, etc.). For  
13 the stand-alone services, the respective price ranges were derived from real  
14 market prices in the canton. Costs were denoted in Swiss francs (CHF) (1  
15 CHF  $\approx$  1 USD or 0.85 EUR as of May 2018). An example for the choice  
16 situations is shown in figure 1. The wording of the introductory texts for the  
17 DCEs can be found in the appendix.

18 For public transportation, the second attribute is the number of zones<sup>4</sup>  
19 (i.e. geographical units for pricing purposes). The price for season tickets in  
20 the canton increases linearly with the number of included zones (CHF 30 per  
21 additional zone for a second class ticket). The price was capped at five zones,  
22 because tickets with more than five zones are valid in the whole canton. The  
23 GA travelcard is valid for the whole country. Real market prices for monthly  
24 season tickets range from CHF 65 to 550<sup>5</sup>, and the prices in the experiment  
25 ranged from CHF 20 to 650.

26 The car-sharing service included a prespecified number of kilometers per  
27 month. The local car-sharing company “Mobility” charges by time and dis-  
28 tance. Only distance was chosen as a measure to simplify the experiment  
29 and because it is the main cost driver of the service. Constraints were im-  
30 posed on the design such that the displayed attribute levels imply a cost per  
31 kilometer of 0.4 - 2.8 CHF/km. The local car-sharing company charges from  
32 CHF 0.55 to 1.05 CHF/km (depending on the type of car). The cost was  
33 higher in the experiment in order to cover a higher WTP range and because

---

<sup>4</sup>Public transportation services in the canton of Zurich are united in a public transportation association, “ZVV”. ZVV offers season tickets that are valid for a certain number of zones. Within the purchased zones, all public transportation services can be used.

<sup>5</sup>See <https://www.zvv.ch/> and <https://www.sbb.ch/> for price information.

1 time was ignored as a factor.

2 Bicycle-sharing was included as a monthly subscription service with cost  
3 and included hours per month as attributes. Two free-floating bicycle-sharing  
4 companies, “LimeBike” and “O-Bike”, were active in Zurich in May 2018 with  
5 prices of CHF 2 and CHF 3 per hour. PubliBike, a station-based service,  
6 was priced at CHF 6 per hour (without annual subscription). CHF 1.4 - 6.7  
7 was chosen as the range of implied prices for the experiment.

8 E-bike-sharing in Zurich is provided by two companies “PubliBike” and  
9 “Smide,” the latter being directed at the high-end market (and only available  
10 in the city of Zurich, not in the whole canton). Without a subscription, prices  
11 range from CHF 9 - 15 per hour. CHF 5 - 43 per hour was chosen for the  
12 experiment.

13 The park and ride service in the experiment included a prespecified num-  
14 ber of days at all SBB train stations. Park and ride parking spots in the  
15 canton of Zurich that were included cost CHF 0 - 15 per day. The attribute  
16 levels implied prices of CHF 1.4 - 14.2 per day.

17 The price per minute for taxi services in Zurich ranges from CHF 1  
18 (UberX) to CHF 2.5 (Uber Black, which is comparable to other taxi ser-  
19 vices). The prices in the experiment range from CHF 0.5 to CHF 5.

20 The car-sharing and park and ride experiments were only displayed to  
21 study participants with a driver’s licence. For the bundles, the car-sharing  
22 and the park and ride attribute were interacted with driver’s licence owner-  
23 ship in the statistical model in order to make the WTP values comparable.

24 Table 3 shows the attributes and attribute levels of the DCE for trans-  
25 portation service bundles. Participants completed 18 choice tasks. The num-  
26 ber of attribute levels was reduced to limit the number of choice tasks (in  
27 order to limit the total response burden of the survey).

Table 2: DCEs for stand-alone transportation services: attributes and attribute levels. All participants completed all DCEs, participants without driver’s licence were excluded from the DCE for park and ride and car-sharing.

Experiment	Attributes	Levels	# Choice tasks
1. Public transportation	Cost (CHF/mo)	50, 120, 180, 240, 360, 500, 650	18
	Validity (level)	1-2, 3, 4, 5, all, GA	
2. Car-sharing	Cost (CHF/mo)	30, 70, 100, 200, 350	10
	Kilometres included	50, 75, 125, 150	
3. Park and Ride	Cost (CHF/mo)	10, 20, 50, 100, 150, 200	12
	Days/mo	4, 7, 14	
4. Bicycle-sharing	Cost (CHF/mo)	5, 10, 20, 30, 40, 60	12
	Hours/mo included	3, 5, 7, 10	
5. E-bike-sharing	Cost (CHF/mo)	20, 60, 100, 150, 200, 300	12
	Hours/mo included	3, 5, 7, 10	
6. Taxi	Cost (CHF/mo)	15, 30, 60, 150, 300, 600	12
	Minutes/mo included	30, 60, 120	

Table 3: DCE for transportation service bundles (pure bundles): attributes and levels.

Experiment	Attributes	Unit	Levels
Bundle	Cost	CHF/mo	150, 200, 300, 400, 900, 1800

Figure 1: Example choice situations for individual services (a) and service bundles (b).

1 *3.3. Statistical Modelling and WTP Calculation*

2 To analyze the results of the experiment, a mixed logit model was used.  
3 The advantage of mixed logit is that it does not exhibit the restrictive in-  
4 dependence of the irrelevant alternatives property and can be generalized  
5 to accommodate repeated choices by decision makers. Thus, correlations  
6 of unobserved factors from the decision makers can also be accommodated.  
7 As shown by Train (2009), the panel structure of the data can be taken  
8 into account by letting coefficients vary over decision makers, but not over  
9 choice situations. Thus, the utility of an alternative  $j$  for decision maker  $n$  in  
10 choice situation  $t$  can be expressed as  $U_{njt} = \beta_n x_{njt} + \epsilon_{njt}$ . The conditional  
11 likelihood that a participant makes a sequence of choices in time periods  
12  $\mathbf{i} = \{i_1, \dots, i_T\}$  can then be written as  $L_{ni}(\beta) = \prod_{t=1}^T \left[ \frac{e^{\beta_n x_{ni_t t}}}{\sum_j e^{\beta_n x_{njt}}} \right]$  and the  
13 unconditional probability is  $P_{ni} = \int L_{ni}(\beta) f(\beta) d\beta$ .

14 The estimation of the WTP in the case of the mixed logit model is not  
15 as straightforward as in the multinomial logit case, as the parameters are  
16 random variables. Sillano and Ortúzar (2005) discussed four methods for  
17 estimating the the WTP from population parameters: a) ratio of population  
18 means, b) simulation, c) log-normal distribution for WTP and d) fixing the  
19 cost coefficient. Taking the ratio of population means does not result in a  
20 mean WTP value, but a WTP for the average individual and thus the ap-  
21 proach is only recommended to test model specification. Using a log-normal  
22 distribution for parameters is also not recommended as this tends to result  
23 in very large WTP values. The simulation approach involves taking random  
24 draws from the parameters' distributions, calculating the ratio, and repeat-  
25 ing the process many times to sample the WTP distribution. The spread  
26 of the WTP distribution obtained by simulation can be very large and thus,  
27 researchers often constrain the distribution in practice. Hensher and Greene  
28 (2003) showed that there is no behavioral justification for constraining the  
29 distribution except for the sign of the WTP and that using the constrained  
30 distribution is not better or worse than using the unconstrained distribution.  
31 Sillano and Ortúzar (2005) criticized the approach not because of this issue,  
32 but because of the fact that values are simulated for people that do not exist  
33 in the first place. In the models estimated by Sillano and Ortúzar (2005),  
34 fixing the cost coefficient led to an overestimation of the WTP distribution.  
35 However, Revelt and Train (2000) put forward the following arguments for  
36 fixing the cost coefficient: (1) mixed logit models tend to be unstable when  
37 all parameters are random, (2) with a fixed price coefficient, coefficient ra-

1 tios follow the same distribution as the coefficient of the attribute, and (3)  
2 as the price coefficient is necessarily negative, the choice of the respective  
3 distribution can be problematic (a log-normal distribution may result in ex-  
4 tremely high WTP values). Sillano and Ortúzar (2005) themselves estimated  
5 individual-level parameters using the Bayesian approach and stressed the ad-  
6 vantage that the approach may allow identification of study participants that  
7 did not respond seriously. Greene et al. (2005) pointed out that using a clas-  
8 sical approach to estimate individual WTP values were as straightforward as  
9 the Bayesian approach and both approaches have merit. Another approach  
10 to investigate WTP is to estimate models in WTP space instead of preference  
11 space. The concept was first introduced by Cameron and James (1987) and  
12 Cameron (1988) and was investigated in Train and Weeks (2005). Train and  
13 Weeks (2005) found that models in preference space fit the data better, but  
14 models in WTP space resulted in more reasonable distributions of WTP.

15 In this paper, a fixed cost coefficient was used and thus, the WTP distri-  
16 bution was derived from the distributions of the non-cost coefficients. The  
17 mean and standard deviation of the WTP distribution were the mean and  
18 standard deviation of the non-cost coefficient divided by the cost coefficient.  
19 The reason for using a fixed cost coefficient was the greater stability of the  
20 models, because a consistent and robust method was required to estimate all  
21 seven DCE models.

## 1 4. Results

### 2 4.1. Model Estimation: Stand-Alone Services and Bundled Services

3 Table 4 shows the result of the mixed logit model estimations for the  
4 stand-alone transportation services. The cost coefficient was fixed, and the  
5 coefficients describing the respective extent of service and the opt-out coeffi-  
6 cient were assumed to follow a normal distribution. The model fit compared  
7 to the null model was good for public transportation (pseudo  $R^2$  of 0.38), and  
8 very good for the other services (pseudo  $R^2$  greater than 0.5 for all services).  
9 The cost coefficients were negative for all experiments, which was expected.  
10 The coefficients for the respective services were all positive, except for the  
11 taxi subscription.

12 Table 5 shows the estimation results for the transportation service bun-  
13 dles. All coefficients were highly significant. The coefficients for the extent of  
14 service were positive for the smartphone application, public transportation,  
15 car-sharing and park and ride, which was expected. For bicycle-sharing, e-  
16 bike-sharing and taxi, the coefficients were negative. The model fit was very  
17 good with a pseudo  $R^2$  of 0.62.

1 *4.2. WTP Estimation and Comparison*

2 Table 6 shows the WTP values for the stand-alone services and for the  
 3 same services in a pure bundle. WTP1 is the mean value of the full WTP  
 4 distribution, but for WTP2 only the positive values of the WTP distribution  
 5 were considered. Public transportation, car-sharing and park and ride were  
 6 valued higher in a bundle than as stand-alone services. Bicycle-sharing, e-  
 7 bike-sharing and taxi were valued lower. The average WTP for taxi services  
 8 was negative, indicating that the average consumer did not wish to purchase  
 9 a monthly taxi subscription (neither as stand-alone service, nor bundled with  
 10 other services). The sum of the valuations were CHF 51.6 and CHF 102.2  
 11 (WTP1 and WTP2, respectively) for the stand-alone services and CHF 93.7  
 12 and 155.9 for the bundled services. The WTP for the smartphone application  
 13 that integrates all services into a journey planner and acts as the ticketing  
 14 and payment system was valued at CHF 104 and CHF 127 (WTP1 and  
 15 WTP2, respectively).

16 Figure 2 and figure 3 show the density functions of the WTP distributions  
 17 for the stand-alone services and the bundled services, respectively. The plots  
 18 indicated that for the bundled services, bicycle-sharing, e-bike-sharing and  
 19 taxi were not suitable because only a small fraction of WTP values were  
 20 positive.

Table 6: WTP comparison: stand-alone services versus bundled services

Attribute	Stand-alone services		Pure bundle	
	WTP1	WTP2	WTP1	WTP2
Smartphone App	-	-	103.9	127
Public Transportation	46	77.4	120.2	139.7

Park and Ride	2.9	6.7	7.6	7.9
Bicycle-sharing	0.8	3.4	-15.2	(2.6)
E-bike-sharing	2.6	11.9	-18.8	(3.3)
Taxi	-1.2	1.6	-2.4	(0.1)

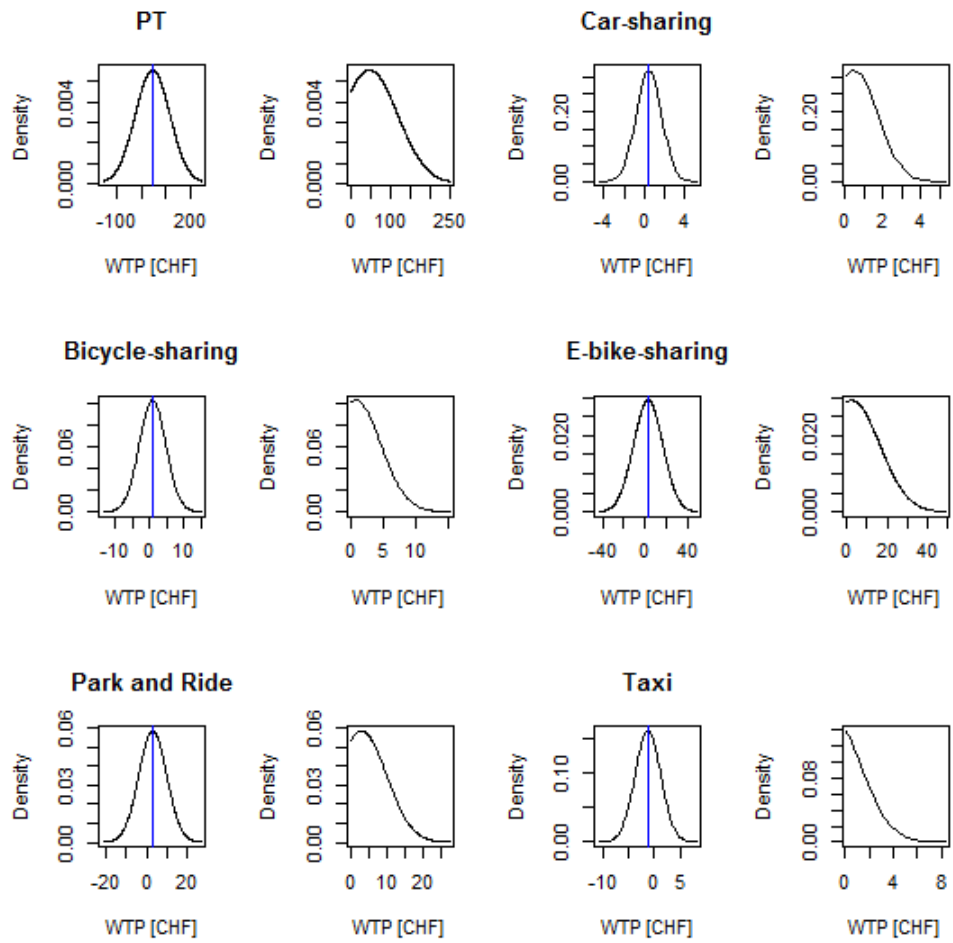

Figure 2: WTP distributions of stand-alone transportation services.

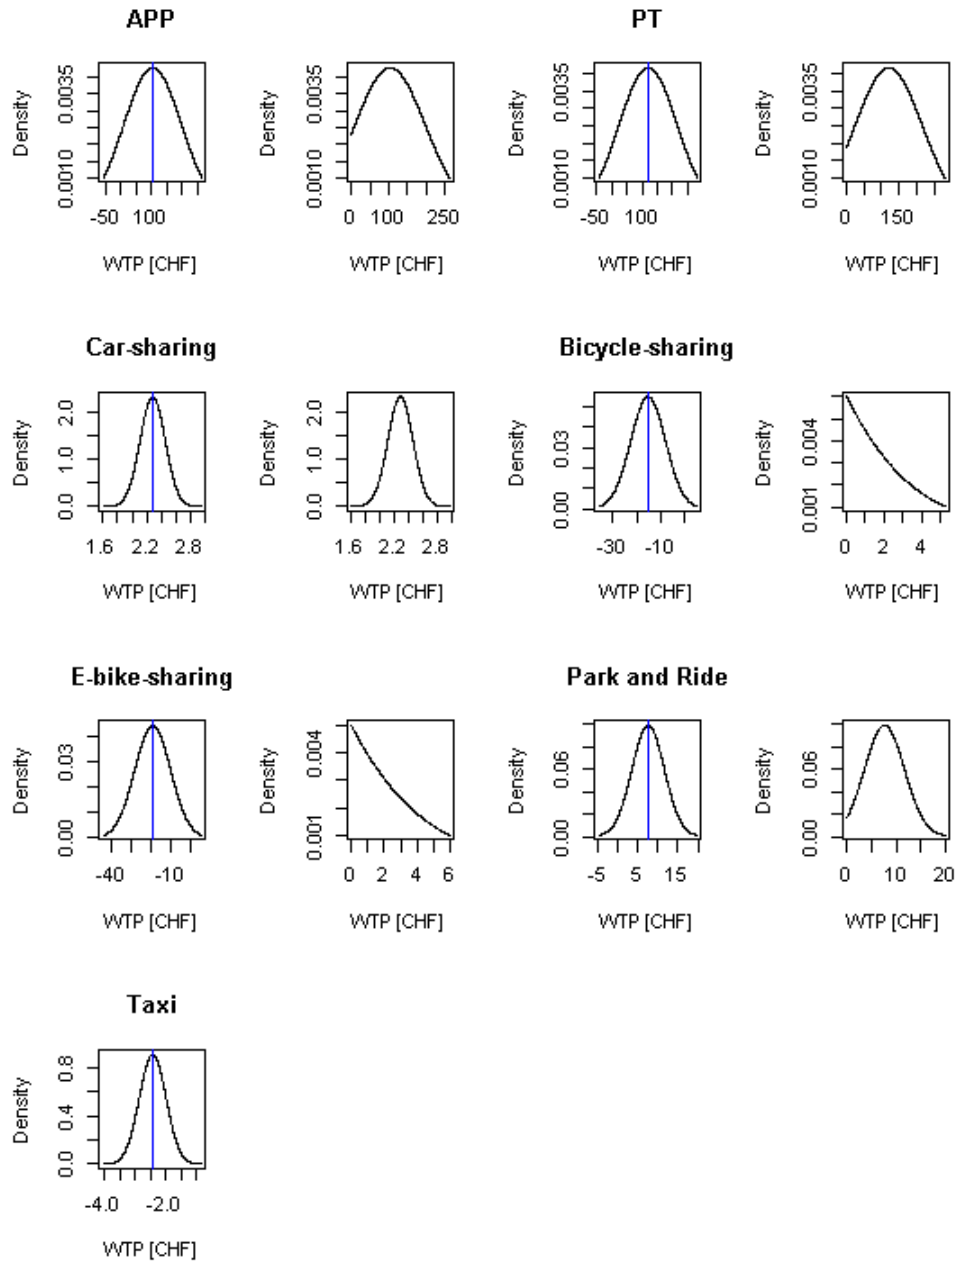

Figure 3: WTP distributions of bundled transportation services.

## 1 5. Discussion

2 The results of the WTP estimation indicated that the sum of the valua-  
3 tions of the services were higher in bundles than as stand-alone services. This  
4 is mainly due to the significantly higher valuation of public transportation  
5 in the bundles. Car-sharing and park and ride were also valued higher in  
6 bundles than as stand-alone services. This is most likely due to the fact that  
7 public transportation, car-sharing, and park and ride services are complemen-  
8 tary services. In most cases, park and ride is only feasible in combination  
9 with public transportation. Car-sharing complements public transportation  
10 for destinations with low public transportation service quality, for leisure  
11 trips, and for the transportation of heavy goods. This is consistent with  
12 the observation that shared modes rely on high quality public transporta-  
13 tion systems (Stillwater et al., 2009; Becker et al., 2017). The valuation  
14 of bicycle-sharing, e-bike-sharing and taxi services were lower in a bundle  
15 and the WTP1 values for these services in bundles were even negative. The  
16 negative WTP values are a result of the assumption that coefficients are  
17 normally distributed. However, the negative coefficients are not necessarily  
18 behaviorally unreasonable. If a service provides no utility to a consumer but  
19 is part of a bundle, consumers may perceive the price of the bundle as too  
20 high, and may even subtract the valuation of the service from the price of  
21 the bundle. Thus, a larger extent of service that provides no utility may  
22 be perceived as negative. Not all study participants will exhibit such choice  
23 behavior. However, if some do, this could be an explanation for the negative  
24 sign. Furthermore, bicycle-sharing, e-bike-sharing, and taxi were all services  
25 with a very low market share. It is therefore likely that these services indeed  
26 provide no utility for the majority of users in the sample. This could be due  
27 to individual preferences or due to limited availability of the these services  
28 in the main activity space of the consumers.

29 Consequently, offering pure bundles that include low-share transportation  
30 modes may not be an optimal strategy for mobility providers. As an alter-  
31 native strategy, a bundle of only public transportation, car-sharing and park  
32 and ride could be offered and the smartphone application that integrates the  
33 services could be designed such that low-share transportation modes can be  
34 purchased on a pay-as-you-go basis. By bundling products in such a way,  
35 the higher WTP for public transportation in bundles could still be exploited.  
36 For consumers that choose the bundle, the advantage is guaranteed access to  
37 the bundled services without the burden of thinking of the loss each time a

1 service is consumed. The notion that multiple losses are perceived as more  
2 negative than a single loss is illuminated by prospect theory and mental ac-  
3 counting (Drumwright, 1992; Gaeth et al., 1990; Yadav, 1994). The higher  
4 WTP of consumers for bundled services could therefore be rooted in avoid-  
5 ing multiple losses. This would be interesting to test in future research on  
6 individuals with a higher income, and thus a lower price sensitivity.

7 The WTP for the smartphone application is comparatively high, even for  
8 the Swiss price level. There are two conceivable reasons for this: the features  
9 of the app, or the fact that participants attached too much weight to the app  
10 compared to the other attributes. The description of the app included the  
11 following features: ICT and price integration of all services, ticket integra-  
12 tion, a comprehensive multimodal journey planner and the analysis of travel  
13 behavior in the background to provide suggestions to optimize personal travel  
14 (e.g. in terms of cost). The app was also described as being able to show  
15 the positions of shared vehicles and the occupancy of parking spots. The  
16 comprehensive set of features that are not yet part of any journey planner  
17 in Switzerland could be the reason for the high WTP. However, it cannot be  
18 excluded that participants simply attached too much weight to the attribute  
19 because it was the first attribute or because it was the only attribute partic-  
20 ipants do not have experience with (as all other services of the bundle exist  
21 in the real market in a similar form).

22 In Switzerland, there are no examples of comprehensive product bundling,  
23 but there are trials with price bundling. The national train company (SBB)  
24 offers a mobility package called “SBB Greenclass”<sup>6</sup> (Becker et al., 2018).  
25 Greenclass includes a 1st class GA travelcard, a BMW i3, park and ride, car-  
26 sharing, bicycle-sharing, and vouchers for taxi journeys (total value of CHF  
27 250). The price of SBB Greenclass for a contract period of one year is CHF  
28 1310 per month and it is thus directed at high income customers. The stand-  
29 alone services cost CHF 1389 per month without the parking subscription  
30 (the price of which highly depends on the location). It would cost CHF 599  
31 for an equivalent BMW i3 subscription from a different provider, CHF 525  
32 for the 1st class GA travelcard, CHF 15 for an equivalent car-sharing and  
33 bicycle-sharing subscription and CHF 250 for the taxi vouchers. There is

---

<sup>6</sup>Prices for the current offer that are slightly different than in the reference given above can be found here: [www.sbb.ch/en/travelcards-and-tickets/railpasses/greenclass.html](http://www.sbb.ch/en/travelcards-and-tickets/railpasses/greenclass.html), last accessed: July 2018.

1 no significant integration of the services, thus SBB Greenclass is an example  
2 of price bundling. Although the price is clearly lower than the sum of the  
3 stand-alone prices, the individual services cannot be consumed at the same  
4 time (thus for many customers the price may be too high relative to the  
5 ability to utilize the services). Nevertheless, the trial of SBB Greenclass was  
6 a success, which indicates that there are customer groups with a significant  
7 WTP for bundles. The reason could also include the aforementioned low price  
8 sensitivity of high income customers, combined with a WTP for a “carefree”  
9 solution.

10 Traditional public transportation season tickets are already bundles if  
11 they include several public transportation services. For example, the GA  
12 travel card in Switzerland is valid for passenger boats, as well as funicular  
13 railways, buses, trams and trains and existing journey planners integrate  
14 these services. In Switzerland and in many other places, ticket, price and  
15 ICT integration is thus already a reality for collective public transportation.  
16 The difference to MaaS schemes is that MaaS also integrates personal trans-  
17 portation services that are available to the public (i.e. taxi, car-sharing,  
18 bicycle-sharing etc.), which necessitates more advanced ICT solutions. Sup-  
19 ply of personal transportation services is more distributed, and availability  
20 cannot readily be predicted by the customer. ICT systems provide utility by  
21 filling the information gap and by assisting coordination between customers  
22 and mobility service providers.

## 1 **6. Conclusion**

2 In this paper, the WTP differences between stand-alone and bundled  
3 services were investigated. The results indicated that the WTP for public  
4 transportation, car-sharing and park and ride services were higher in bundles.  
5 Bicycle-sharing, e-bike-sharing and taxi services in a bundle were valued  
6 lower compared to stand-alone counterparts. The results have implications  
7 for mobility providers that seek to offer transportation service bundles. Of-  
8 fering pure bundles that include low-share transportation modes, which are  
9 not perceived directly as complementary to public transportation were not  
10 effective. Instead, low-share transportation modes should be included on a  
11 pay-as-you-go basis. The results also indicate that consumers exhibit a com-  
12 paratively high WTP at CHF 104 - 127 for a smartphone application that  
13 integrates the services, manages ticketing and payment and makes sugges-  
14 tions to optimize personal travel.

15 So called “Mobility as a Service” concepts can be seen as a special case  
16 of service bundling and previous research in marketing and production eco-  
17 nomics should be taken into account. Literature on product and service  
18 bundling provides concise terminology and bundle classification methodol-  
19 ogy.

20 The effects of mobility behavior, attitude toward to the environment and  
21 technological commitment were not yet investigated and will be subject to  
22 future research, as each relates to the purchase likelihood of bundles. Further-  
23 more, different user segments could in the future be considered. Additional  
24 research on the topic of ICT-enabled service bundling could draw from ques-  
25 tions raised in the bundling literature. These topics include the legality and  
26 optimality of bundling strategies, the effect of competition on the bundling  
27 decision, and consumers’ perception of bundles.

28 Furthermore, the environmental impact of transportation service bundling  
29 is still unclear. On the one hand, ICT-enabled transportation service bundles  
30 could lead to a reduction of private vehicle-miles and reduce car ownership  
31 (and thereby reduce the associated life-cycle emissions). On the other hand,  
32 they could also invite overconsumption of mobility services, which could offset  
33 potential positive environmental effects. This should be investigated before  
34 claims about positive effects of transportation service bundling are made.

## 8 **Appendix A. DCEs: introductory information for participants**

9 Each experiment was introduced with an introductory text. The following  
10 subsections contain the translated texts.

### 11 *Appendix A.1. Stand-alone service: general introduction*

12 Please read the following information carefully.  
13 You will be presented with two different mobility services (option 1 and  
14 option 2). Please decide whether you would purchase the service at the  
15 given price or not (i.e. decline).

16 Remarks:

- 17 • Please try to decide the same way as you would in the real world.  
18 Decline offers that you would not purchase.
- 19 • Assume that you could only purchase the service at the given price and  
20 that there would be no other way to purchase the service.

21 Tip:

- 22 • If you are using a smartphone to complete the survey, please use it in  
23 landscape mode.

### 24 *Appendix A.2. Stand-alone service: public transportation*

25

26 Possible choices:

- 27 • Validity: ZVV area (1-2 zones, 3 zones, 4 zones, 5 zones, all zones) or  
28 the whole country (GA travel card).

- 1       • Second class ticket

2   Remarks:

- 3       • The zones for the cities of Winterthur (120) and Zurich (110) count as  
4       two zones.
- 5       • In case you already possess a public transportation season ticket, as-  
6       sume that it expired and that the offer is to renew it.

7   (Figure: map of pt zones)

8   *Appendix A.3. Stand-alone service: car-sharing*

9       The car-sharing season ticket provides access to a car-sharing service.  
10      The service allows you to access 3000 vehicles at 1500 locations in the whole  
11      country. The vehicles can be booked in advance. The service includes a  
12      credit of 50, 75, 125 or 150 kilometers per month.

13   Possible choices:

- 14       • Credit: 50, 75, 125 or 150 kilometers per month.

15   Remark:

- 16       • In case you already possess a car-sharing subscription, assume that it  
17       expired and that the offer is to renew it.

18   *Appendix A.4. Stand-alone service: park and ride*

19      A subscription for all park and rail parking spots at SBB train stations.  
20      The service includes access to 500 parking spots in the whole country and  
21      allows for parking at train stations to transfer to the train. The stations  
22      Zurich HB, Zurich Oerlikon and Winterthur are not included.

23   Possible choices:

- 24       • Credit: 4, 7 or 14 days per month.

1 *Appendix A.5. Stand-alone service: bicycle-sharing*

2 A subscription for bicycle-sharing services in the whole country with 2000  
3 bicycles in the canton of Zurich. The service includes a monthly credit.  
4 Bicycles can be left anywhere on public ground and are repositioned several  
5 times per week by the operator such that they are located at central locations.

6

7 Possible choices:

- 8 • Credit: 3, 5, 7 or 10 hours per month.

9 *Appendix A.6. Stand-alone service: e-bike-sharing*

10 A subscription for e-bike-sharing services in the whole country with 400  
11 bicycles in the canton of Zurich. The service includes a monthly credit.  
12 Bicycles can be left anywhere on public ground and are repositioned several  
13 times per week by the operator such that they are located at central locations.

14

15 Possible choices:

- 16 • Credit: 3, 5, 7 or 10 hours per month.

17 *Appendix A.7. Stand-alone service: electric bicycle-sharing*

18 A monthly credit for taxi services in the whole country (in minutes).

19 Possible choices:

- 20 • Credit: 30, 60, 120 minutes per month.

21 *Appendix A.8. Service bundles*

22 Please read the following information carefully.

23 You will be presented with two bundles of mobility services. Please decide  
24 whether you would buy the bundle at the given price or not. If you are already  
25 using one of the services that is included in the bundles, please assume that  
26 you would be reimbursed for that service.

27 The following services are included in the bundles:

28

29 Possible choices:

- 1     • Public transportation: ZVV area (1-2 zones, 3 zones, 4 zones, 5 zones,  
2       all zones) or the whole country (GA travel card).
- 3     • Car-sharing: The car-sharing season ticket provides access to a car-  
4       sharing service. The service includes a credit of 50, 125 kilometers per  
5       month. The service allows you to access 3000 vehicles at 1500 locations  
6       in the whole country.
- 7     • Bicycle-sharing: A subscription for bicycle-sharing services in the whole  
8       country with 2000 bicycles in the canton of Zurich. The service includes  
9       a monthly credit of 3 or 5 hours per month. Bicycles can be left any-  
10      where on public ground and are repositioned several times per week by  
11      the operator such that they are located at central locations.
- 12    • E-bike-sharing: A subscription for e-bike-sharing services in the whole  
13      country with 400 bicycles in the canton of Zurich. The service includes a  
14      monthly credit of 3 or 5 hours per month. Bicycles can be left anywhere  
15      on public ground and are repositioned several times per week by the  
16      operator such that they are located at central locations.
- 17    • Parking sports at train stations (park and ride): A subscription for all  
18      park and rail parking spots at SBB train stations. The service includes  
19      access to 500 parking spots in the whole country and allows for parking  
20      at train stations to transfer to the train. The service includes 4, 7 or  
21      14 days of parking.
- 22    • Taxi subscription: A taxi credit for 30 or 60 minutes for taxi trips in  
23      the whole country.
- 24    • Smartphone app: The app provides a journey planner (similar to Google  
25      maps) that combines the services optimally for each journey. Car-  
26      sharing, bicycle-sharing and parking spots are displayed on a map (incl.  
27      availability and the possibility to book them). Your mobility behavior  
28      is analyzed in the background and you are presented with suggestions  
29      to reach your destinations faster or at a lower cost. You can also indi-  
30      cate personal preferences like walking a prespecified distance by foot or  
31      with a bicycle per week. Payment is managed by the app. Tickets can  
32      be displayed by the app. You also receive a plastic card as a ticket.

33 Remarks:

- 1     • Please try to decide the same way as you would in the real world.
- 2         Decline offers that you would not purchase.
- 3     • Assume that you could still buy the services in the usual way.
