Abstract

Many contemporary theoretic studies of trade over geography reduce to an examination of constant-elasticity reactions to changes in iceberg trade costs. These impacts are readily analyzed in simple constant-returns models based on the Armington (1969) assumption of regionally differentiated goods. Following the line of reasoning suggested by Arkolakis et al. (2008) one can reach the surprising conclusion that industrial organization does not matter. In the present paper, we show that this finding is fragile, and with a minor elaboration of their model, the rich industrial-organization features of the popular Melitz (2003) model do, in fact, generate important differences for trade and welfare.

Keywords: Variety effects; Heterogeneous firms; Gains from trade
JEL classification: F1

1 Introduction

Arkolakis et al. (2008) show that, given appropriate parameterization to match trade responses, many contemporary theoretic models of trade over geography generate equivalent gains from trade. We can push this result further to show equivalence between a

model based on the Melitz (2003) theory of heterogeneous firms and a simple constant-
We show, however, that this result is fragile. Addition of a second sector which competes
for factor services breaks the equivalence. That is, if the elasticity of factor supply to
the traded sector is larger than zero the models will produce divergent assessments of the
impact of commercial policy on trade and welfare.

2 Models

Our analysis begins with two models calibrated to a common benchmark dataset, one
model based on Melitz (2003) and another based on Armington (1969) as elaborated
by Devarajan et al. (1993). In our simulations we include three regions (indexed by \( r \)
or \( s \)). Each region is endowed with a primary factor (labor) which can be used in a
traded sector or directly consumed as leisure. Trade theories concerning these models are
well developed in the literature, so we simply present our notation and the equilibrium
conditions for each model. The theoretical setup employed by Arkolakis et al. (2008)
is a special case of the Melitz model when we parameterize it such that the implied
factor-supply elasticity to the traded sector is zero.\(^1\)

Tables 1 and 2 define our notation, and the algebraic formulation of the alternative
models is presented in Table 3.

Given the initial conditions and values of the fixed parameters, the calibrated pa-
rameters of the Melitz model are found by inverting the equilibrium conditions. The
Armington distribution parameters (the \( \xi_{rs} \)) are calculated such that the Armington and
Melitz models have identical benchmark trade flows.

In the calibration we choose labor and welfare units such that the initial wages and
ture-cost-of-living indexes are one; \( w^0_r = c^0_r = 1 \). This is a convenient choice because it

\(^1\)Our setup is equivalent to having a second constant-returns sector which uses only labor. The labor
supply elasticity to the traded sector is zero either when the value share of the non-traded sector is zero
or when preferences are Cobb-Douglas.

Table 2: Parameters

**Fixed parameters:**
- Pareto shape parameter: $a = 3.4$
- Pareto lower support: $b = 0.2$
- Substitution elasticity Melitz varieties: $\sigma_M = 3.8$
- Substitution elasticity Armington varieties: $\sigma_A = 4.4 (= a + 1)$
- Probability of firm death: $\delta = 0.05$
- Value share of traded sector: $\gamma = 0.5$
- Labor endowment $\bar{L} = 2/3$

**Instruments:**
- Iceberg trade-cost factor: $\tau_{rs}$
- Top-level substitution elasticity between traded and non-traded goods: $\alpha$

**Assumed initial conditions:**
- Benchmark home-market trade cost factor: $\tau_{rr}^0 = 1.0$
- Benchmark external-market trade cost factor: $\tau_{rs}^0 = 2.0$ ($\forall r \neq s$)
- Benchmark number of entered firms: $m_r^0 = 10$
- Benchmark number of operating home firms: $n_r^0 = 9.5$
- Benchmark number of operating export firms: $n_{rs}^0 = 0.6$ ($\forall r \neq s$)

**Calibrated parameters:**
- Fixed operating-cost on $r$ to $s$ link: $f_{rs}$
- Fixed cost of productivity draw: $f_r^c$
- Preference weight on traded sector: $\psi_T$
- Preference weight on non-traded sector: $\psi_L$
- Armington bilateral CES weights: $\xi_{rs}$

</tbody>
</table>

a If \( \alpha = 1 \) this reverts to the familiar Cobb-Douglas form.
simplifies our calculation of the elasticity of labor supply available to the traded sector of the economy. The relevant residual labor supply function is given by

$$g(w_r) = \bar{L}_r - \psi L - \frac{Y_r}{e_r(w_r)} \left( \frac{e_r(w_r)}{w_r} \right)^\alpha,$$

which is derived from equation (9a). Substituting in the unit expenditure function and $Y_r = w_r \bar{L}_r$, and then calculating the elasticity evaluated at the benchmark ($w = e(w) = 1$), yields

$$\eta = (1 - \gamma)(\alpha - 1) = \frac{\alpha - 1}{2}.$$  

(13)

So, we use the instrument, $\alpha$, to control the implied labor-supply elasticity. If we set $\alpha = 1$ then the elasticity is zero and we have a model that is consistent with Arkolakis et al. (2008).²

3 Experiment and Results

In order to compare the Armington versus Melitz models we compute a simple experiment where we eliminate iceberg trade costs between regions one and two. Using the instrument $\alpha$, we control the implied labor-supply elasticity ($\eta$) faced by the trade sectors. Setting the Armington elasticity as suggested by Arkolakis et al. (2008) ($\sigma_A = a + 1$), we find that the welfare impacts of removing the iceberg costs are different across the models, except in the special case that the implied labor-supply elasticity is exactly zero.

Figure 1 plots the region-1 welfare impact of reductions in trade-costs as a function of the implied labor-supply elasticity. Notice that the welfare impacts are only equivalent at $\eta = 0$. The results for region 2 are identical to region 1, because of the symmetry built into our illustrative model. Figure 2 shows the welfare impacts on the third region for the same set of experiments. Although the curves in Figure 2 intersect twice, it is only

²We also ran experiments where we fixed $\alpha = 3$ and calibrated $\gamma$ to the assumed labor-supply elasticity. Again, at values of $\eta$ above zero the models did not generate the same results. It is only in the special case that $\gamma = 1$ is equivalence between the Armington and Melitz models is obtained.
at $\eta = 0$ that we have equivalence in the models across the multiregion equilibrium.

One key feature of the environment set up by Arkolakis et al. (2008) is that the number of entered firms is unaffected by changes in iceberg costs. Labor supply is perfectly inelastic so all of the adjustments in firm revenues and number of operating firms shows up in the wage. Changes in nominal entry costs are mirrored by changes in expected profits, so equation (6) is satisfied with no changes in $M_r$. At $\eta \neq 0$, however, the wage only partially absorbs the adjustments in the industrial organization and $M_r$ changes. In Table 4 we present the basic industrial organization in the Melitz model in the benchmark and in scenarios with different labor supply responses. At $\eta = 1$ we have entry as labor is drawn into the Melitz sector.

At $\eta = 0$ Table 4 shows the “anti-variety effect” emphasized by Baldwin and Forslid (forthcoming) where the new import varieties generated by trade liberalization are more than offset by lost domestic varieties. Notice, however, that the total number of varieties consumed in region 1 goes from 10.69 in the benchmark to 11.77 in the scenario, when $\eta = 1$. The anti-variety effect is dominated when there is enough response in factor

</table>
supplies. Feenstra (forthcoming) emphasizes, however, that because these varieties enter the expenditure system at different prices we cannot simply count up varieties and infer variety gains or losses. Feenstra shows that variety gains, when comparing equilibriums \( t \) versus \( t - 1 \), are given by deviations in the ratio \( (\lambda_t^r/\lambda_{t-1}^r)^{-1/(\sigma_M-1)} \) from unity, where \( \lambda_t^r \) represents region-\( r \)’s share of expenditures at equilibrium \( z \) on goods available in both equilibria to the total expenditures at \( z \). We confirm the Feenstra (forthcoming) analytical result that there are no import-variety gains or losses in the Melitz structure (for the case that \( \eta = 0 \)), but we find that the variety gains reemerge when we allow resources to be drawn into the Melitz sector.

To emphasize fundamental differences between the Armington and Melitz models we look at trade flows. In the case that \( \eta = 0 \) the trade patterns before and after the removal of trade costs are identical. One might think that \( \sigma_A \) parameter can be set to match the trade reactions in the Melitz model when \( \eta \neq 0 \), but this is not the case. If we adjust \( \sigma_A \) to match some of the Melitz-model trade flows the errors on other flows in the bilateral matrix become larger. (Norman (1990) reached a similar conclusion nearly 20 years ago.)

4 Conclusion

Arkolakis et al. (2008) analyze a single sector model with heterogeneous-firms and concluded that new theories “do not really offer new gains from trade, given observed trade levels.” We replicate this finding in comparing Armington and Melitz formulations with iceberg trade costs. Provided that the labor supply elasticity is zero and the Armington elasticity of substitution equal to one plus the Melitz Pareto-shape parameter, these models are identical. This result is, however, fragile. If the labor-supply elasticity is different than zero the industrial organization begins to matter. Firm entry and import variety effects become important if the labor-supply elasticity is not zero.
