# 1 Introduction & Summary ...

In a paper from 1985 K. Schüchel and Hk. Müller-Buschbaum report about the reduced and mixed valence niobate  $\text{Sr}_5\text{Nb}_5\text{O}_{16}$  [1]. Small amounts of small crystals were obtained by a special technique which comprises the use of a  $\text{H}_2 / \text{H}$  plasma. The crystals were studied by single crystal x-ray diffraction and energy-dispersive x-ray spectroscopy. The crystal structure of  $\text{Sr}_5\text{Nb}_5\text{O}_{16}$  is perovskite-related, layered, orthorhombic, and non-centrosymmetric. Physical properties are not reported.

In a paper from 2008 F. Lichtenberg et al. present the realization that  $\text{Sr}_5\text{Nb}_5\text{O}_{16} \triangleq \text{SrNbO}_{3.2}$  represents an oxygen-deficient variant of  $\text{Sr}_5\text{Nb}_5\text{O}_{17} \triangleq \text{SrNbO}_{3.4}$  with fully ordered oxygen vacancies [2]. The crystal structure of  $\text{Sr}_5\text{Nb}_5\text{O}_{17} \triangleq \text{SrNbO}_{3.4}$  is perovskite-related, layered, orthorhombic, and centrosymmetric [3].

$\text{Sr}_5\text{Nb}_5\text{O}_{17} \triangleq \text{SrNbO}_{3.4}$  is an  $n = 5$  type member of the homologous series  $A_nB_nO_{3n+2} \triangleq ABO_x$  and a quasi-1D metal, see Refs. [2 – 5] and references therein.

$A_nB_nO_{3n+2} \triangleq ABO_x$  represent a homologous series of perovskite-related layered oxides and are meanwhile called Carpy-Galy phases. The layers comprise an arrangement of  $\text{BO}_6$  octahedra which are  $[110]_{\text{perovskite}}$  oriented along the  $c$ -axis.

The index or structure type  $n$  describes the thickness of the layers which are  $n$   $BO_6$  octahedra thick along the  $c$ -axis. For  $n = \infty$  the non-layered perovskite structure  $ABO_3$  is obtained.

A sketch of their crystal structure and compositional examples are presented on pages 10 - 15.

The following items are examples why oxides of the type  $A_nB_nO_{3n+2} \triangleq ABO_x$  are interesting, see Refs. [2 – 8] and references therein:

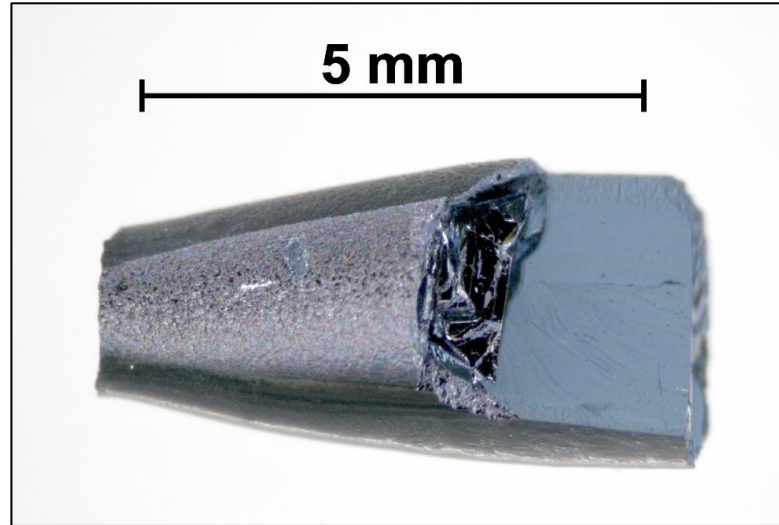

- In contrast to most layered materials they display a pronounced structural anisotropy also within the layers which extend along the  $ab$ -plane
- They comprise the highest- $T_c$  ferroelectrics such as the  $n = 4$  type  $La_4Ti_4O_{14} \triangleq La_2Ti_2O_7 \triangleq LaTiO_{3.5}$  with  $T_c = 1770$  K
- They comprise quasi-1D metals in which the delocalized electrons are embedded in a ferroelectric-like environment such as the  $n = 5$  type  $Sr_5Nb_5O_{17} \triangleq SrNbO_{3.4}$  and some of the quasi-1D metals are most probably polar or ferroelectric quasi-1D metals
- Many compounds can be synthesized in a single phase and crystalline form via a solidification from the melt by using the floating zone technique
- They might have a potential to create superconductors and / or multiferroics

- There are many possible chemical compositions including non-stoichiometric compounds
- The quasi-1D metals  $\text{SrNbO}_{3.45}$  ( $n = 4.5$ ) and Sr- and O-deficient  $\text{Sr}_{0.95}\text{NbO}_{3.37}$  ( $n = 5$ ) were studied by special optical techniques which revealed the presence of photoinduced metastable dd-exciton-driven metal-to-insulator transitions
- The Sr- and O-deficient  $n = 5$  type quasi-1D metal  $\text{Sr}_{0.95}\text{NbO}_{3.37}$  was studied by resonant soft x-ray scattering which revealed the presence of two distinct and simultaneous charge density waves along the non-metallic c-axis

The already mentioned  $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{68} \triangleq \text{Sr}_5\text{Nb}_5\text{O}_{17} \triangleq \text{SrNbO}_{3.4}$  and  $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{64} \triangleq \text{Sr}_5\text{Nb}_5\text{O}_{16} \triangleq \text{SrNbO}_{3.2}$  represent another interesting topic and associated comments and open questions are presented on pages 225 – 227 in part 6.7 of Ref. [5]. The quasi-1D metal  $\text{Sr}_5\text{Nb}_5\text{O}_{17} \triangleq \text{SrNbO}_{3.4}$  can be prepared via the melt by using the floating zone technique but attempts to prepare  $\text{Sr}_5\text{Nb}_5\text{O}_{16} \triangleq \text{SrNbO}_{3.2}$  in the same way were not successful [2, 5]. Meanwhile, however, the synthesis of related materials in a single phase and crystalline form via the melt by using the floating zone technique is reported in a paper from 2020, namely  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  and  $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$  [5]. They are called Sr- and O-deficient  $n = 5$  type Carpy-Galy phases of the Schückel-Müller-Buschbaum type.

## Introduction & Summary 4 / 13

The availability of melt-grown  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  and  $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$  leads to several comments and open questions which are presented in part 6.9.8 of Ref. [5]. The topic of this work is  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  and here we present from Ref. [5] some pictures of the melt-grown material:

The magnetic susceptibility  $\chi(T)$  of melt-grown  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  and  $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$  indicates that they are quasi-1D metals like  $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$  [5]. The reported non-centrosymmetric space group for  $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{64} \cong \text{Sr}_5\text{Nb}_5\text{O}_{16}$  [1] suggests that  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  and  $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$  are likewise non-centrosymmetric.

If a non-centrosymmetric crystal structure can be experimentally confirmed, then  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  and  $\text{Sr}_{17}\text{Ca}_2\text{Nb}_{19}\text{WO}_{64}$  are most probably polar or ferroelectric quasi-1D metals.  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  was studied with respect to the question if its crystal structure is non-centrosymmetric or centrosymmetric and this paper presents the results.

The following pages 10 – 14 present some sketches of the crystal structure of Carpy-Galy phases  $A_nB_nO_{3n+2} \triangleq ABO_x$ , compositional examples from the system  $\text{SrNbO}_x$ , and sketches of the crystal structure of  $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{68} \triangleq \text{Sr}_5\text{Nb}_5\text{O}_{17} \triangleq \text{SrNbO}_{3.4}$  and  $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{64} \triangleq \text{Sr}_5\text{Nb}_5\text{O}_{16} \triangleq \text{SrNbO}_{3.2}$

The crystal structure of the  $n = 5$  (II) type  $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$

Three-dimensional representation of the non-centrosymmetric crystal structure of  $\text{SrNbO}_{3.2} \triangleq \text{Sr}_5\text{Nb}_5\text{O}_{16} \triangleq \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$  from the paper of K. Schückel and Hk. Müller-Buschbaum [1].

The O ions are depicted as small open balls, the Nb ions as small black balls, and the Sr ions as large open balls. The hatched objects represent the  $\text{NbO}_6$  octahedra.

The definition of the specified a-, b-, and c-axis is not the same as in the paper from K. Schückel and Hk. Müller-Buschbaum but in agreement with the used definition on the previous pages.

First it was intended to study the melt-grown  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  (sample No. 838) by single crystal x-ray diffraction. However, it was not possible to prepare from the melt-grown material small crystals with a suitable size and shape because the material displays a pronounced cleavage behavior. It suggests the presence of a particular weak bond strength between the layers that might result from the Sr- and O vacancies which are most probably located at the boundary of the layers.

Then it was tried to study the melt-grown  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  by electron diffraction.

An analysis of melt-grown  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  by Scanning Electron Microscopy (SEM), Energy-Dispersive x-ray Spectroscopy (EDS), and Transmission Electron Microscopy (TEM) indicates the presence of a single phase material. This is in accordance with the results from an analysis by powder x-ray diffraction [5].

The similarity of the non-centrosymmetric structure (space group  $\text{Pmn}2_1$  / No. 31) and centrosymmetric structure (space group  $\text{Pnnm}$  / No. 58) makes a symmetry analysis difficult.

The simulation of the powder x-ray diffraction pattern of the parent compounds  $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$  (centrosymmetric, space group Pnmm / No. 58) and  $\text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$  (non-centrosymmetric, space group Pmn2<sub>1</sub> / No. 31) indicates the presence of peaks in the non-centrosymmetric phase which do not appear in the centrosymmetric phase. Based on those reflections a lamella was prepared with an [100] orientation by using the Focused Ion Beam (FIB) technique. That allows the detection of those specific peaks in the low symmetry phase by comparing the results of simulated and experimental of the electron diffraction patterns of the respective structures acquired by TEM.

Both experimental and simulated diffraction results show that the (050) peak, a characteristic Bragg peak of the non-centrosymmetric structure, which is absent in the centrosymmetric structure, can be observed in the experimental electron diffraction pattern. It indicates that the melt-grown material  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  displays a non-centrosymmetric structure. The magnetic susceptibility  $\chi(T)$  of  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$  suggests it is a quasi-1D metal [5] and because of its non-centrosymmetric structure it is most probably a polar or ferroelectric quasi-1D metal.

Note: On this page and in part 3 the above-mentioned (050) peak refers to a definition where the b-axis is the longest axis, whereas on pages 5, 6, and 10 – 15 and in Refs. [2, 4 – 8] the c-axis is defined as the longest axis

## 2 Experimental ...

## Experimental

From a piece of the melt-grown material some lamellae for TEM investigations were prepared by the Focused Ion Beam (FIB) technique using a dual beam Gallium FIB-SEM of the type FEI Helios 600i. The Energy-dispersive X-ray Spectroscopy (EDS) was performed in another SEM.

Transmission Electron Microscopy (TEM) and Scanning Transmission Electron Microscopy (STEM) experiments were performed with a JEOL F200 STEM / TEM at 200 kV. Simulation of TEM images were performed with the JEMS simulation package, and STEM images with the Dr. Probe software.

# Wyckoff positions continued ...

## Wyckoff Positions Splitting for group - subgroup pair $Pn\bar{m}(58) > Pmn2_1(31)$

The group subgroup chain you want to consider is characterized by:

- an index 2;
- a transformation matrix which relates the coordinate system of the subgroup to that of the supergroup:
- $\begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ -1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 \\ 1/4 \\ 0 \end{bmatrix}$

### Wyckoff positions of group $Pn\bar{m}(58)$

Only bold Wyckoff positions are considered according to unit cell

WP	Representatives
8h	x,y,z
<b>4g</b>	<b>x,y,0</b>
4f	0,1/2,z
4e	0,0,z
<b>2d</b>	<b>0,1/2,1/2</b>
2c	0,1/2,0
<b>2b</b>	<b>0,0,1/2</b>
<b>2a</b>	<b>0,0,0</b>

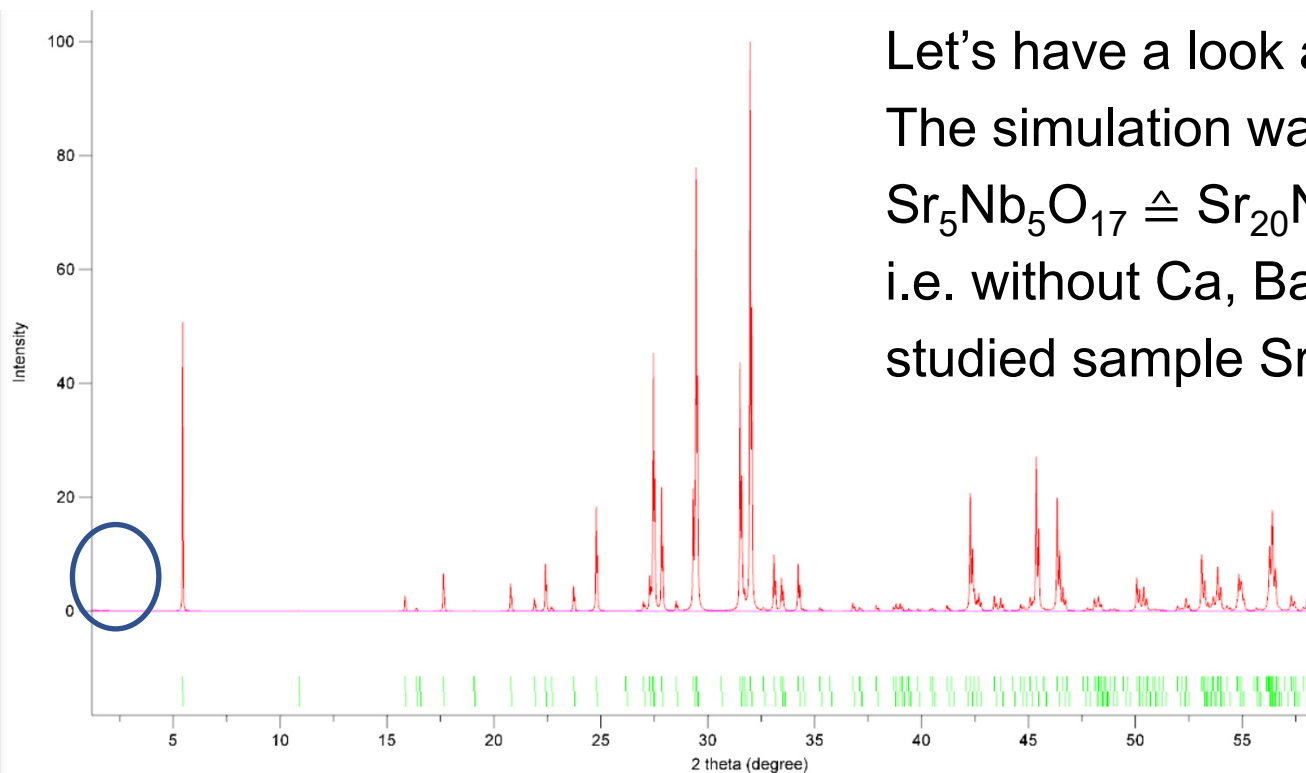

### Result from splitting

No	Wyckoff position(s)	
	Group	Subgroup
1	4g	2a 2a
2	2d	2a
3	2b	2a
4	2a	2a

→ From a symmetry analysis of the parent-child groups it is difficult to draw a conclusion on which specific Wyckoff position we should look at because the low symmetry structure (space group No. 31) has only the Wyckoff position 2a for all elements

# Simulation of the powder x-ray diffraction pattern by VESTA Version 3.5.8 \*

Let's have a look at missing reflections in the two unit cells. The simulation was done with respect to  $\text{Sr}_5\text{Nb}_5\text{O}_{17} \triangleq \text{Sr}_{20}\text{Nb}_{20}\text{O}_{68}$  and  $\text{Sr}_5\text{Nb}_5\text{O}_{16} \triangleq \text{Sr}_{20}\text{Nb}_{20}\text{O}_{64}$ , i.e. without Ca, Ba, W, and the Sr-deficiencies in the studied sample  $\text{Sr}_{17}\text{CaBaNb}_{19}\text{WO}_{64}$

ICSD database code 54058:  $\text{Sr}_5\text{Nb}_5\text{O}_{17}$

According to ICSD 48207 the first peak at  $2\Theta = 2.71^\circ$  is indexed with  $(h\ k\ l) = (0\ 1\ 0)$

ICSD database code 48207:  $\text{Sr}_5\text{Nb}_5\text{O}_{16}$

\* VESTA: <https://jp-minerals.org/vesta/en>

# Simulation of the powder x-ray diffraction pattern by VESTA Version 3.5.8 \*

ICSD database code 54058:  $\text{Sr}_5\text{Nb}_5\text{O}_{17}$

According to  
ICSD 48207  
the second peak  
at  $2\Theta = 13.62^\circ$   
is indexed with  
(h k l) = (0 5 0)

ICSD database code 48207:  $\text{Sr}_5\text{Nb}_5\text{O}_{16}$

\* VESTA: <https://jp-minerals.org/vesta/en>

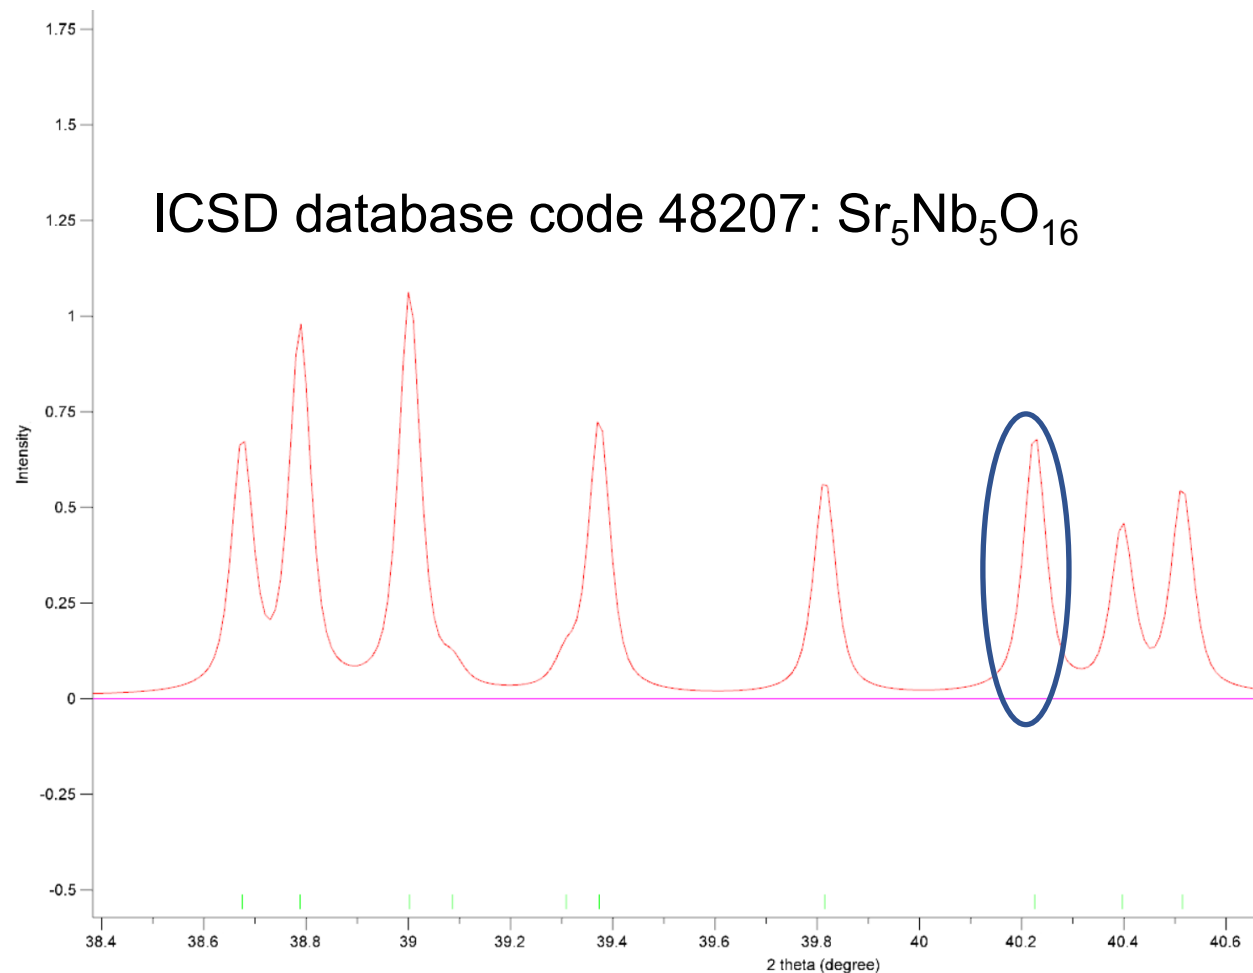

# Simulation of the powder x-ray diffraction pattern by VESTA Version 3.5.8 \*

ICSD database code 54058:  $\text{Sr}_5\text{Nb}_5\text{O}_{17}$

According to  
ICSD 48207  
the peak at  
 $2\Theta = 40.22^\circ$   
is indexed with  
 $(h\ k\ l) = (1\ 12\ 0)$

ICSD database code 48207:  $\text{Sr}_5\text{Nb}_5\text{O}_{16}$

\* VESTA: <https://jp-minerals.org/vesta/en>

## Experimental electron diffraction patterns obtained from two different areas of the lamella

The observations from XRD and electron diffraction pattern simulations match well with the [100] or [001] direction, even if the intensities in the second image are slightly different. Based on EBSD the lamella was prepared with an electron beam parallel to the a-axis, i.e. along the [100] direction

## Experimental (left) and simulated (right) electron diffraction pattern

They show the match of the diffraction spots. As expected the intensities in the experimental pattern is slightly different from that in the simulated pattern because of the additional elements Ca, Ba, W and the Sr-deficiencies in the lattice and the slight tilt of the sample.

Space group  $P m n 2_1$  (No. 31)

# 4 Author contributions ...

## **Author contributions**

Ali Baghi Zadeh performed the SEM and TEM experiments and simulations and prepared a report about the results of the crystallographic studies.

Frank Lichtenberg provided pieces of the melt-grown material and its powder x-ray diffraction data and prepared this paper in form of a presentation by using Ali Baghi Zadeh's report and parts of Ref. [5].

Christian Zaubitzer prepared from the melt-grown material some lamellae by the FIB technique.

Luiz Grafulha Morales performed the EBSD experiments and analysis.

Arkadiy Simonov tried to prepare from the melt-grown material small crystals which are suitable for single crystal x-ray diffraction.

# 5 Acknowledgement ...

## **Acknowledgement**

Nicola Spaldin and Frank Lichtenberg thank the ETH Zurich for financial support.

Frank Lichtenberg thanks Nicola Spaldin for her support, Marc Petitmermet for his IT support, and Susanne Blatter for her administrative support.

Ali Baghi Zadeh acknowledges the access to computational resources and software for image analysis at ScopeM.
