Main subjects: flow visualization
Fluid: subsonic and supersonic jets
Visualization method(s): shear interferometry,
Other keywords: light sources, coherence

ABSTRACT: *The high aperture shear interferometer is presented. Due to the use of synthesized coherence elements, it was possible to remove the limitation on the size of the light source, which allowed to get rid of the slit diaphragm. The pictures of visualization of plane subsonic and supersonic jets are given. This method will be especially in demand in the visualization of fast processes, where the illumination of a phase object is most necessary.*

1 Introduction

To date, a number of publications have appeared on the possibility of allocating optical inhomogeneities in the cross-section of a light beam probing a gas medium [1]. They talk about the prospects of using the method of synthesized coherence, which was previously used in astronomy to detect exoplanets [2], to visualization of gas-dynamic flows. In these publications, we are talking about the synthesized coherence of the light source, which can be locally created in a particular section of the light beam probing the inhomogeneity region. In this case, the interference pattern recorded by the system will characterize the local inhomogeneity in the cross-section, rather than represent the integral inhomogeneity throughout the beam, as it was before. It should be noted that all experiments on the implementation of this principle were carried out in the laboratory under atmospheric air density and single – pass scheme (light source on the one hand, the receiver-on the other). Under these conditions, it was possible to achieve localization of phase inhomogeneity within 20 cm, which is clearly insufficient for gas-dynamic studies on aerodynamic stands. So far, the method of synthesized coherence has not reached the level required to highlight the inhomogeneity of the flow in the required section (order of at least 1 cm) of the tested model. However, the elements of the method of synthesized coherence, implemented in the illuminator of the shear interferometer, allowed to obtain an interference pattern without a slit diaphragm, which significantly expanded the possibility of high-speed recording of the observed process due to the increase in the luminous flux of the illuminator by using a wide light source.

The problem of illumination of the measuring volume in shadow and interference devices used for visualization of gas-dynamic flows is particularly acute when registering fast-flowing processes. If we limit ourselves to continuous light sources that do not require synchronization with the recording system and therefore require minimal adaptation, laser sources provide the greatest illumination to date. For Fig. 1 the process of shot from an air gun (4 consecutive frames), registered with the help of a shadow device IAB-455, was presented, a laser with a power of 1 W was used as an illuminator (Fig. 2).

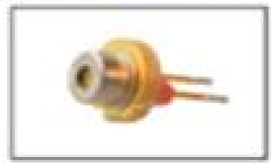
LD-445-1000MG



TECHNICAL DATA

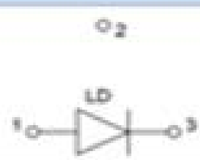
Blue Laser Diode

Features

- Multi Transverse Mode
- Peak Wavelength: 445 nm
- Optical Ouput Power: 1W
- Package: 5.6 mm, dismounted

Electrical Connection

Pin Configuration



m-type

PIN	Function
1	LD Anode
2	n.c
3	LD Cathode

Bottom View

Absolute Maximum Ratings (T_C=25°C)

Item	Symbol	Value	Unit
LD Reverse Voltage	V_R (LD)	4.5	V
LD Forward Current	I_F	1.4	A
Operating Case Temperature	T_C	0 ... +35	°C
Storage Temperature	T_{stg}	-30 ... +70	°C

Specifications (T_C=25°C, I_{OP}=1.05A)

Item	Symbol	Min.	Typ.	Max.	Unit
Optical Specifications

Figure 2

This laser (LD-445-1000MG) has a low coherence, which has a positive effect on the quality of the picture, but the need for a slit diaphragm does not allow the full use of all the available light flux.

2. System description and results

Organization "Rosinterf" together with TSAGI has developed a basic two-pass interferometric system based on a IAB-451 collimator and IT183 interferometer with testing light wave synthesized coherence. Optical scheme of the system is presented on Fig. 3.Interferometer schematicis presented on Fig. 4/ Aerodynamic stand appearance is shown on Fig. 5, 6.

3. Summary

The presented results demonstrate the possibility of gas-dynamic flows visualization in the interferometric system without the slit diaphragm. The slit diaphragm absence increases test medium luminosity by several orders of magnitude. This approach has great potential for visualization of fast flows.
